gmacgrp_rxwatchdogerror Fields

Bit	Name	Description	Access	Reset
31:0	cnt	This field indicates the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes or value programmed in Register 55 (Watchdog Timeout Register)).	RO	0x0

18.7.1.104. gmacgrp_rxcverror

Register 120 (Receive Frame Count for Receive Error Frames)
This register maintains the number of frames received with error because of the GMII/MII RXER error. While "Receive Error" is applicable to all PHY interfaces, "Frame Extension Error" can occur only for PHY interfaces that support 1G half-duplex mode.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF8001E0
i_emac_emac1	0xFF802000	0xFF8021E0

gmacgrp_rxctrlframes_g Fields

Bit	Name	Description	Access	Reset
31:0	cnt	This field indicates the number of good control frames received.	RO	0x0

18.7.1.106. gmacgrp_mmc_ipc_receive_interrupt_mask

This register maintains the mask for the interrupt generated from the receive IPC statistic counters.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800200
i_emac_emac1	0xFF802000	0xFF802200
i_emac_emac2	0xFF804000	0xFF804200

Offset: 0x200

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

18.7.1.107. gmacgrp_mmc_ipc_receive_interrupt

This register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop

Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32-bits wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (bits[7:0]) must be read to clear the interrupt bit.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800208
i_emac_emac1	0xFF802000	0xFF802208
i_emac_emac2	0xFF804000	0xFF804208

Offset: 0x208

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

18.7.1.137. gmacgrp_layer4_address0

Register 257 (Layer 4 Address Register 0)

You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option in coreConsultant. If the Layer 3 and Layer 4 Address Registers are configured to be double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

gmacgrp_l3_l4_control2 Fields

Bit	Name	Description	Access	Reset
21	l4dpim2	When set, this bit indicates that the Layer 4 Destination Port number field is enabled for inverse matching. When reset, this bit indicates that the Layer 4 Destination Port number field is enabled for perfect matching. This bit is valid and applicable only when Bit 20 (L4DPM0) is set high.	RW	0x0
20	l4dpm2	When set, this bit indicates that the Layer 4 Destination Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Destination Port number field for matching.	RW	0x0
19	l4spim2	When set, this bit indicates that the Layer 4 Source Port number field is enabled for inverse matching. When reset, this bit indicates that the Layer 4 Source Port number field is enabled for perfect matching.	RW	0x0

continued...

Bit	Name	Description	Access	Reset
		This bit is valid and applicable only when Bit 18 (L4SPM2) is set high.		
18	l4spm2	When set, this bit indicates that the Layer 4 Source Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Source Port number field for matching.	RW	0x0
16	l4pen2	When set, this bit indicates that the Source and Destination Port number fields for UDP frames are used for matching. When reset, this bit indicates that the Source and Destination Port number fields for TCP frames are used for matching. The Layer 4 matching is done only when either L4SPM2 or L4DPM2 bit is set high.	RW	0x0
15:1 1	l3hdbm2	IPv4 Frames: This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: Bits [12:11] of this field correspond to Bits [6:5] of L3HSBM2, which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 frames. The following list describes the concatenated values of the L3HDBM2[1:0] and L3HSBM2 bits: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 127: All bits except MSb are masked. This field is valid and applicable only if L3DAM2 or L3SAM2 is set high.	RW	0x0
10:6	l3hsbm2	Layer 3 IP SA Higher Bits Match IPv4 Frames: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: This field contains Bits [4:0] of the field that indicates the number of higher bits of IP Source or Destination Address matched in the IPv6 frames. This field is valid and applicable only if L3DAM2 or L3SAM2 is set high.	RW	0x0
5	l3daim2	When set, this bit indicates that the Layer 3 IP Destination Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 4 (L3DAM2) is set high.	RW	0x0
continued...				

Bit	Name	Description	Access	Reset
4	l3dam2	When set, this bit indicates that Layer 3 IP Destination Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When Bit 0 (L3PEN2) is set, you should set either this bit or Bit 2 (L3SAM2) because either IPv6 DA or SA can be checked for filtering.	RW	0x0
3	l3saim2	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 2 (L3SAM2) is set high.	RW	0x0
2	l3sam2	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When Bit 0 (L3PEN2) is set, you should set either this bit or Bit 4 (L3DAM2) because either IPv6 SA or DA can be checked for filtering.	RW	0x0
0	l3pen2	When set, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv6 frames. When reset, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv4 frames. The Layer 3 matching is done only when either L3SAM2 or L3DAM2 bit is set high.	RW	0x0

18.7.1.149. gmacgrp_layer4_address2

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

4	l3dam3	When set, this bit indicates that Layer 3 IP Destination Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When Bit 0 (L3PEN3) is set, you should set either this bit or Bit 2 (L3SAM3) because either IPv6 DA or SA can be checked for filtering.	RW	0x0
continued...				

Bit	Name	Description	Access	Reset
3	l3saim3	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 2 (L3SAM3) is set high.	RW	0x0
2	l3sam3	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When Bit 0 (L3PEN3) is set, you should set either this bit or Bit 4 (L3DAM3) because either IPv6 SA or DA can be checked for filtering.	RW	0x0
0	l3pen3	When set, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv6 frames. When reset, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv4 frames. The Layer 3 matching is done only when either L3SAM3 or L3DAM3 bit is set high.	RW	0x0

18.7.1.155. gmacgrp_layer4_address3

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

18.7.1.160. gmacgrp_hash_table_reg0

This register contains the first 32 bits of the hash table. The 256-bit Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming frame is passed through the CRC logic and the upper eight bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 8b'10111111 selects Bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bitwise reversal for the value obtained in Step 1.
3. Take the upper 8 bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. If the Bit 1 (Pass All Multicast) is set in Register 1 (MAC Frame Filter), then all multicast frames are accepted regardless of the multicast hash values.

Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the Hash Table Register X registers are written.

Note: Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Register 353 (VLAN Tag Inclusion or Replacement Register)

The VLAN Tag Inclusion or Replacement register contains the VLAN tag for insertion or replacement in the transmit frames.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800584
i_emac_emac1	0xFF802000	0xFF802584
i_emac_emac2	0xFF804000	0xFF804584

Offset: 0x584

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
reserved_31_20 RO 0x0												csvl RW 0x0	vlp RW 0x0	vlc RW 0x0	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
vlt RW 0x0															

gmacgrp_vlan_incl_reg Fields

Bit	Name	Description	Access	Reset
31:20	reserved_31_20	Reserved	RO	0x0
19	csvl	C-VLAN or S-VLAN When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted frames. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the transmitted frames.	RW	0x0
18	vlp	VLAN Priority Control When this bit is set, the control Bits [17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, the mti_vlan_ctrl_i control input is used, and Bits [17:16] are ignored.	RW	0x0
17:16	vlc	VLAN Tag Control in Transmit Frames * 2'b00: No VLAN tag deletion, insertion, or replacement * 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted frames with VLAN tags. * 2'b10: VLAN tag insertion The MAC inserts VLT in bytes 15 and 16 of the frame after inserting the Type value (0x8100/0x88a8) in bytes 13 and 14. This operation is performed on all transmitted frames, irrespective of whether they already have a VLAN tag. * 2'b11: VLAN tag replacement The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted frames (Bytes 13 and 14 are 0x8100/0x88a8). Note: Changes to this field take effect only on the start of a frame. If you write this register field when a frame is being transmitted, only the subsequent frame can use the updated value, that is, the current frame does not use the updated value.	RW	0x0
15:0	vlt	VLAN Tag for Transmit Frames This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority, Bit 12 is the CFI/DEI, and Bits[11:0] are the VLAN tag's VID field.	RW	0x0

18.7.1.169. gmacgrp_vlan_hash_table_reg

The 16-bit Hash table is used for group address filtering based on VLAN tag when Bit 18 (VTHM) of Register 7 (VLAN Tag Register) is set. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on Bit 16 (ETV) of VLAN Tag Register) in the incoming frame is passed through the CRC logic and the upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the VLAN tag or ID (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
 2. Perform bitwise reversal for the value obtained in Step 1.
 3. Take the upper four bits from the value obtained in Step 2.
- If the corresponding bit value of the register is 1'b1, the frame is accepted.

Otherwise, it is rejected. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) of this register are written.

Notes:

* Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

18.7.1.171. gmacgrp_sub_second_increment

In the Coarse Update mode (TSCFUPDT bit in Register 448), the value in this register is added to the system time every clock cycle of clk_ptp_ref_i. In the Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800704
i_emac_emac1	0xFF802000	0xFF802704
i_emac_emac2	0xFF804000	0xFF804704

Offset: 0x704

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								ssinc RW 0x0							

gmacgrp_sub_second_increment Fields

Bit	Name	Description	Access	Reset
7:0	ssinc	The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time-Nanoseconds register has an accuracy of 1 ns (TSCTRLSSR bit is set). When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465ns. In this case, you should program a value of 43 (0x2B) that is derived by 20ns/0.465.	RW	0x0

18.7.1.172. gmacgrp_system_time_seconds

The System Time -Seconds register, along with System-TimeNanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to l3_sp_clk).

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800708

Bit	Name	Description	Access	Reset
		<p>This behavior is because of the non-linear toggling of bits in the digital rollover mode in Register 451 (System Time - Nanoseconds Register).</p> <p>Flexible PPS0 Output (ptp_pps_o[0]) Control</p> <p>Programming these bits with a non-zero value instructs the MAC to initiate an event. Once the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The Software should ensure that these bits are programmed only when they are all-zero. The following list describes the values of PPSCMD0:</p> <ul style="list-style-type: none"> • 0000: No Command • 0001: START Single Pulse This command generates single pulse rising at the start point defined in Target Time Registers (register 455 and 456) and of a duration defined in the PPS0 Width Register. • 0010: START Pulse Train This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by 'STOP Pulse train at time' or 'STOP Pulse Train immediately' commands. • 0011: Cancel START This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time. • 0100: STOP Pulse train at time This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses. • 0101: STOP Pulse Train immediately This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010). • 0110: Cancel STOP Pulse train This command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command. • 0111-1111: Reserved 		

18.7.1.182. gmacgrp_auxiliary_timestamp_nanoseconds

This register, along with Register 461 (Auxiliary Timestamp Seconds Register), gives the 64-bit timestamp stored as auxiliary snapshot. The two registers together form the read port of a 64-bit wide FIFO with a depth of 16. Multiple snapshots can be stored in this FIFO. The ATSNS bits in the Timestamp Status register indicate the fill-level of this FIFO. The top of the FIFO is removed only when the last byte of Register 461 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800730

18.7.1.190. gmacgrp_mac_address18_high

Register 516 (MAC Address18 High Register)

The MAC Address18 High register holds the upper 16 bits of the 19th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address18 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address18 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800810
i_emac_emac1	0xFF802000	0xFF802810

18.7.1.196. gmacgrp_mac_address21_high

Register 522 (MAC Address21 High Register)

The MAC Address21 High register holds the upper 16 bits of the 22nd 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address21 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address21 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800828

18.7.1.202. gmacgrp_mac_address24_high

Register 528 (MAC Address24 High Register)

The MAC Address24 High register holds the upper 16 bits of the 25th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address24 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address24 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800840

18.7.1.208. gmacgrp_mac_address27_high

Register 534 (MAC Address27 High Register)

The MAC Address27 High register holds the upper 16 bits of the 28th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address27 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address27 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address

18.7.1.214. gmacgrp_mac_address30_high

Register 540 (MAC Address30 High Register)

The MAC Address30 High register holds the upper 16 bits of the 31st 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address30 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address30 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800870

18.7.1.220. gmacgrp_mac_address33_high

Register 546 (MAC Address33 High Register)

The MAC Address33 High register holds the upper 16 bits of the 34th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address33 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address33 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800888
i_emac_emac1	0xFF802000	0xFF802888
i_emac_emac2	0xFF804000	0xFF804888

Offset: 0x888

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

The MAC Address40 High register holds the upper 16 bits of the 41st 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address40 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address40 Low Register must be performed after at least four clock cycles in the destination clock domain.

18.7.1.278. gmacgrp_mac_address62_high

Register 604 (MAC Address62 High Register)

The MAC Address62 High register holds the upper 16 bits of the 63rd 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address62 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address62 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800970
i_emac_emac1	0xFF802000	0xFF802970
i_emac_emac2	0xFF804000	0xFF804970

Offset: 0x970

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

The MAC Address69 High register holds the upper 16 bits of the 70th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address69 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address70 Low Register must be performed after at least four clock cycles in the destination clock domain.

18.7.1.336. gmacgrp_mac_address91_high

Register 662 (MAC Address91 High Register)

The MAC Address91 High register holds the upper 16 bits of the 92nd 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address32 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address91 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800A58
i_emac_emac1	0xFF802000	0xFF802A58
i_emac_emac2	0xFF804000	0xFF804A58

Offset: 0xA58

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

18.7.1.394. gmacgrp_mac_address120_high

Register 719 (MAC Address120 High Register)

The MAC Address120 High register holds the upper 16 bits of the 6-byte 121st MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address120 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address120 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800B40
i_emac_emac1	0xFF802000	0xFF802B40
i_emac_emac2	0xFF804000	0xFF804B40

Offset: 0xB40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

18.7.1.408. gmacgrp_mac_address127_high

Register 733 (MAC Address127 High Register)

The MAC Address127 High register holds the upper 16 bits of the 128th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address127 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address127 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800B78
i_emac_emac1	0xFF802000	0xFF802B78
i_emac_emac2	0xFF804000	0xFF804B78

Offset: 0xB78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

		Value	Description		
		0x0	CLEARST		
		0x1	RESET		

18.7.1.411. dmagrp_transmit_poll_demand

Register 1 (Transmit Poll Demand Register)

The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory. When this register is read, it always returns zero.

Module Instance	Base Address	Register Address

If that descriptor is not available (owned by the Host), the transmission returns to the Suspend state and the Bit 2 (TU) of Register 5 (Status Register) is asserted. If the descriptor is available, the transmission resumes.</p>	RW	0x0

18.7.1.412. dmagrp_receive_poll_demand

Register 2 (Receive Poll Demand Register)

The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns. When this register is read, it always returns zero.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF801008

Bit	Name	Description	Access	Reset
31:0	rpd	<p>Receive Poll Demand</p> <p>When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 19 (Current Host Receive Descriptor Register). If that descriptor is not available (owned by the Host), the reception returns to the Suspended state and the Bit 7 (RU) of Register 5 (Status Register) is not asserted. If the descriptor is available, the Rx DMA returns to the active state.</p>	RW	0x0

18.7.1.413. dmagrp_receive_descriptor_list_address

Register 3 (Receive Descriptor List Address Register)

The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given.

You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR

bit to 1, the DMA takes the newly programmed descriptor base address.

If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF80100C
i_emac_emac1	0xFF802000	0xFF80300C
i_emac_emac2	0xFF804000	0xFF80500C

Offset: 0x100C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit	Name	Description	Access	Reset
31:2	rdesla_32bit	This field contains the base address of the first descriptor in the Receive Descriptor list. The LSB bits (1:0) are ignored (32-bit wide bus) and internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO).	RW	0x0

18.7.1.414. dmagr_transmit_descriptor_list_address

Register 4 (Transmit Descriptor List Address Register)

The Transmit Descriptor List Address register points to the start of the Transmit Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, Bit 13 (ST) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly programmed descriptor base address.

If this register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF801010
i_emac_emac1	0xFF802000	0xFF803010

18.7.1.415. dmagr_p_status

Register 5 (Status Register)

The Status register contains all status bits that the DMA reports to the host. The Software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The bits of this register are not cleared when read. Writing 1'b1 to (unreserved) Bits[16:0] of this register clears these bits and writing 1'b0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in Register 7 (Interrupt Enable Register).

0	ti	Transmit Interrupt This bit indicates that the frame transmission is complete. When transmission is complete, Bit 31 (OWN) of TDES0 is reset, and the specific frame status information is updated in the descriptor.	RW	0x0

18.7.1.416. dmagrp_operation_mode

Register 6 (Operation Mode Register)

The Operation Mode register establishes the Transmit and Receive operating modes and commands. This register should be the last CSR to be written as part of the DMA initialization. This register is also present in the GMAC-MTL configuration with unused and reserved bits 24, 13, 2, and 1.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF801018
i_emac_emac1	0xFF802000	0xFF803018
i_emac_emac2	0xFF804000	0xFF805018

Offset: 0x1018

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

18.7.1.417. dmagrp_interrupt_enable

Register 7 (Interrupt Enable Register)

The Interrupt Enable register enables the interrupts reported by Register 5 (Status Register). Setting a bit to 1'b1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF80101C
i_emac_emac1	0xFF802000	0xFF80301C
i_emac_emac2	0xFF804000	0xFF80501C

Offset: 0x101C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

18.7.1.418. dmagrp_missed_frame_and_buffer_overflow_counter

Register 8 (Missed Frame and Buffer Overflow Counter Register)

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the host buffer being unavailable. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF801020
i_emac_emac1	0xFF802000	0xFF803020
i_emac_emac2	0xFF804000	0xFF805020

Offset: 0x1020

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

dmagrps_receive_interrupt_watchdog_timer Fields

Bit	Name	Description	Access	Reset
31:8	reserved_31_8	Reserved	RO	0x0
7:0	riwt	RI Watchdog Timer Count This bit indicates the number of system clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the Rx DMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per RDES1[31] of any received frame.	RW	0x0

18.7.1.420. dmagrps_axi_bus_mode

The AXI Bus Mode Register controls the behavior of the AXI master. It is mainly used to control the burst splitting and the number of outstanding requests.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF801028
i_emac_emac1	0xFF802000	0xFF803028

18.7.1.426. dmagrps_hw_feature

Register 22 (HW Feature Register)

This register indicates the presence of the optional features or functions of the DWC_gmac. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF801058
i_emac_emac1	0xFF802000	0xFF803058
i_emac_emac2	0xFF804000	0xFF805058

Offset: 0x1058

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

18.7.2.7. ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0818
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1018
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1818

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTNTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

18.7.2.8. INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C081C
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C101C
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C181C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTON CMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTON OVF 0x0	Reserved							INTMO DE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

18.7.2.9. INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0820
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1020
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1820

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved															

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0

18.7.2.31. ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0880
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1080
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1880

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

18.7.2.32. SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0890
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1090
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1890

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				Address RO 0x0											

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
11:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

18.7.3. emac_tx_ecc Address Map

Module Instance	Base Address	End Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0FFF
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C17FF
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1FFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 1161	0x0	32	RO	0x0	
CTRL on page 1162	0x8	32	RW	0x0	ECC Control Register
INITSTAT on page 1163	0xC	32	RW	0x0	This bit is used to set the initialize the memory and ecc to a known value

IP_REV_ID Fields

Bit	Name	Description	Access	Reset
15:0	SIREV	IP Rev # These bits indicate the silicon revision number.	RO	0x0

18.7.3.3. CTRL

ECC Control Register

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C08
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1408
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C08

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INITA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CNT_R STA 0x0	Reserved							ECC_EN 0x0

CTRL Fields

Bit	Name	Description	Access	Reset
16	INITA	Enable for the hardware memory initialization PORTA.	RW	0x0
8	CNT_RSTA	Enable to reset internal single-bit error counter A value to zero	RW	0x0
0	ECC_EN	Enable for the ECC detection and correction logic.	RW	0x0

18.7.3.4. INITSTAT

This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C0C
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C140C
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C0C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															INITCOMPLETEA 0x0

INITSTAT Fields

Bit	Name	Description	Access	Reset
0	INITCOMPLETEA	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0

18.7.3.5. ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C10
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1410
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C10

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

18.7.3.6. ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C14
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1414
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C14

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														SERRINTS 0x0	

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

18.7.3.7. ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C18
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1418
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C18

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTNTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

18.7.3.8. INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C1C
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C141C
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C1C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTON CMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTON OVF 0x0	Reserved							INTMO DE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

18.7.3.9. INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C24
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1424
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C24

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERR A 0x0	Reserved							TSERR A 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

18.7.3.10. MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C28
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1428
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C28

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														CMPFL GA 0x0	

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

18.7.3.11. DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C2C
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C142C
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C2C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address 0x0									

DERRADDRA Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent double-bit error address.	RO	0x0

18.7.3.12. SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C30
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1430
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C30

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Address 0x0							

SERRADDRA Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent single-bit error address.	RO	0x0

18.7.3.13. SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C3C
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C143C
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C3C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

18.7.3.14. ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C40
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1440
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C40

19. USB 2.0 OTG Controller

The hard processor system (HPS) provides two instances of a USB On-The-Go (OTG) controller that supports both device and host functions. The controller supports all high-speed, full-speed, and low-speed transfers in both device and host modes. The controller is fully compliant with the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*. The controller can be programmed for both device and host functions to support data movement over the USB protocol.

The controllers are operationally independent of each other. Each USB OTG controller supports a single USB port connected through a USB 2.0 Transceiver Macrocell Interface Plus (UTMI+) Low Pin Interface (ULPI) compliant PHY. The USB OTG controllers are instances of the Synopsys ⁽⁺⁾DesignWare Cores USB 2.0 Hi-Speed On-The-Go (DWC_otg) controller.

The USB OTG controller is optimized for the following applications and systems: †

- Portable electronic devices †
- Point-to-point applications (no hub, direct connection to HS, FS, or LS device) †
- Multi-point applications (as an embedded USB host) to devices (hub and split support) †

Each of the two USB OTG ports supports both host and device modes, as described in the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*. The USB OTG ports support connections for all types of USB peripherals, including the following peripherals:

- Mouse
- Keyboard
- Digital cameras
- Network adapters
- Hard drives
- Generic hubs

For details on the document revision history of this chapter

19.1. Features of the USB OTG Controller

The USB OTG controller has the following USB-specific features:

- Complies with both Revision 1.3 and Revision 2.0 of the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*
- Supports software-configurable modes of operation between OTG 1.3 and OTG 2.0
- Can operate in Host or Device mode
- Supports multi-point applications with hub and split support
- Supports all USB 2.0 speeds:
 - High speed (HS, 480-Mbps)
 - Full speed (FS, 12-Mbps)
 - Low speed (LS, 1.5-Mbps)

Note: In host mode, all speeds are supported. However, in device mode, only high speed and full speed are supported.

- Integrated scatter-gather DMA supports moving data between memory and the controller
- Supports USB 2.0 in ULPI mode
- Supports all USB transaction types:
 - Control transfers
 - Bulk transfers
 - Isochronous transfers
 - Interrupts
- Supports automatic ping capability
- Supports Session Request Protocol (SRP) and Host Negotiation Protocol (HNP)
- Supports suspend, resume, and remote wake
- Supports up to 16 host channels

Note: In host mode, when the number of device endpoints is greater than the number of host channels, software can reprogram the channels to support up to 127 devices, each having 32 endpoints (IN + OUT), for a maximum of 4,064 endpoints.

- Supports up to 16 bidirectional endpoints, including control endpoint 0
- Note:* Only seven periodic device IN endpoints are supported.
- Supports a generic root hub
- Performs transaction scheduling in hardware

On the USB PHY layer, the USB OTG controller supports the following features:

- 8-bit ULPI PHY data width
- A single USB port connected to each OTG instance
- A ULPI connection to an off-chip USB transceiver
- Software-controlled access, supporting vendor-specific or optional PHY registers access to ease debug
- The OTG 2.0 support for Attach Detection Protocol (ADP) only through an external (off-chip) ADP controller

On the integration side, the USB OTG controller supports the following features:

- Different clocks for system and PHY interfaces
- Dedicated TX FIFO buffer for each device IN endpoint in direct memory access (DMA) mode
- Packet-based, dynamic FIFO memory allocation for endpoints for small FIFO buffers and flexible, efficient use of RAM that can be dynamically sized by software
- Ability to change an endpoint's FIFO memory size during transfers
- Clock gating support during USB suspend and session-off modes
 - PHY clock gating support
 - System clock gating support
- Data FIFO RAM clock gating support
- Local buffering with error correction code (ECC) support

Note: The USB OTG controller does not support the following protocols:

- Enhanced Host Controller Interface (EHCI)
- Open Host Controller Interface (OHCI)
- Universal Host Controller Interface (UHCI)

19.1.1. Supported PHYS

The USB OTG controller only supports USB 2.0 ULPI PHYs. Only the single data rate (SDR) mode is supported.

Refer to the *Device Datasheet* for specific timing information.

19.2. USB OTG Controller Block Diagram and System Integration

Figure 137. USB OTG Controller System Integration

Two subsystems are included in the HPS.

The USB OTG controller connects to the level 3 (L3) interconnect through a slave interface, allowing other masters to access the control and status registers (CSRs) in the controller. The controller also connects to the L3 interconnect through a master interface, allowing the DMA engine in the controller to move data between external memory and the controller.

A single-port RAM (SPRAM) connected to the USB OTG controller is used to store USB data packets for both host and device modes. It is configured as FIFO buffers for receive and transmit data packets on the USB link.

Through the system manager, the USB OTG controller has control to use and test error correction codes (ECCs) in the SPRAM. Through the system manager, the USB OTG controller can also control the behavior of the master interface to the L3 interconnect.

The USB OTG controller connects to the external USB transceiver through a ULPI PHY interface. This interface also connects through pin multiplexers within the HPS. The pin multiplexers are controlled by the system manager.

Additional connections on the USB OTG controller include:

- Clock input from the clock manager to the USB OTG controller
- Reset input from the reset manager to the USB OTG controller
- Interrupt line from the USB OTG controller to the microprocessor unit (MPU) global interrupt controller (GIC).

The USB Controller signals are routed to the dedicated HPS pins.

19.3. USB 2.0 ULPI PHY Signal Description

Table 236. ULPI PHY Interfaces

The ULPI PHY interface is synchronous to the `ulpi_clk` signal coming from the PHY.

Note: For more information on how the USB signals are routed to the HPS I/O, refer to the *HPS Component Interfaces* chapter.

Port Name	Bit Width	Direction	Description
<code>ulpi_clk</code>	1	Input	ULPI Clock Receives the 60-MHz clock supplied by the high-speed ULPI PHY. All signals are synchronous to the positive edge of the clock.
<code>ulpi_dir</code>	1	Input	ULPI Data Bus Control 1—The PHY has data to transfer to the USB OTG controller. 0—The PHY does not have data to transfer.
<code>ulpi_nxt</code>	1	Input	ULPI Next Data Control Indicates that the PHY has accepted the current byte from the USB OTG controller. When the PHY is transmitting, this signal indicates that a new byte is available for the controller.
<code>ulpi_stp</code>	1	Output	ULPI Stop Data Control The controller drives this signal high to indicate the end of its data stream. The controller can also drive this signal high to request data from the PHY.
<code>ulpi_data[7:0]</code>	8	Bidirectional	Bidirectional data bus. Driven low by the controller during idle.

For more information about how the interface signals are routed to the HPS I/O, refer to this chapter.

19.4. Functional Description of the USB OTG Controller

19.4.1. USB OTG Controller Block Description

Figure 138. USB OTG Controller Block Description

Details about each of the units that comprise the USB OTG controller are shown below.

19.4.1.1. Master Interface

The master interface includes a built-in DMA controller. The DMA controller moves data between external memory and the media access controller (MAC).

Properties of the master interface are controlled through the USB L3 Master HPROT Register (`l3master`) in the system manager. These bits provide access information to the L3 interconnect, including whether or not transactions are cacheable, bufferable, or privileged.

Note: Bits in the `l3master` register can be updated only when the master interface is guaranteed to be in an inactive state.

19.4.1.2. Slave Interface

The slave interface allows other masters in the system to access the USB OTG controller's CSRs. For testing purposes, other masters can also access the single port RAM (SPRAM).

19.4.1.2.1. Slave Interface CSR Unit

The slave interface can read from and write to all the CSRs in the USB OTG controllers. All register accesses are 32 bits.

The CSR is divided into the following groups of registers:

- Global
- Host
- Device
- Power and clock gating

Some registers are shared between host and device modes, because the controller can only be in one mode at a time. The controller generates a mode mismatch interrupt if a master attempts to access device registers when the controller is in host mode, or attempts to access host registers when the controller is in device mode. Writing to unimplemented registers is ignored. Reading from unimplemented registers returns indeterminate values.

19.4.1.3. Application Interface Unit

The application interface unit (AIU) generates DMA requests based on programmable FIFO buffer thresholds. The AIU generates interrupts to the GIC for both host and device modes. A DMA scheduler is included in the AIU to arbitrate and control the data transfer between packets in system memory and their respective USB endpoints.

19.4.1.4. Packet FIFO Controller

The Packet FIFO Controller (PFC) connects the AIU with the MAC through data FIFO buffers located in the SPRAM. In device mode, one FIFO buffer is implemented for each IN endpoint. In host mode, a single FIFO buffer stores data for all periodic (isochronous and interrupt) OUT endpoints, and a single FIFO buffer is used for nonperiodic (control and bulk) OUT endpoints. Host and device mode share a single receive data FIFO buffer.

19.4.1.5. SPRAM

An SPRAM implements the data FIFO buffers for host and device modes. The size of the FIFO buffers can be programmed dynamically.

The SPRAM supports ECCs.

19.4.1.6. MAC

The MAC module implements the following functionality:

- USB transaction support
- Host protocol support
- Device protocol support
- OTG protocol support

19.4.1.6.1. USB Transactions

In device mode, the MAC decodes and checks the integrity of all token packets. For valid OUT or SETUP tokens, the following DATA packet is also checked. If the data packet is valid, the MAC performs the following steps:

1. Writes the data to the receive FIFO buffer
2. Sends the appropriate handshake when required to the USB host

If a receive FIFO buffer is not available, the MAC sends a NAK response to the host. The MAC also supports ping protocol.

For IN tokens, if data is available in the transmit FIFO buffer, the MAC performs the following steps:

1. Reads the data from the FIFO buffer
2. Forms the data packet
3. Transmits the packet to the host
4. Receives the response from the host
5. Sends the updated status to the PFC

In host mode, the MAC receives a token request from the AIU. The MAC performs the following steps:

1. Builds the token packet
2. Sends the packet to the device

For OUT or SETUP transactions, the MAC also performs the following steps:

1. Reads the data from the transmit FIFO buffer
2. Assembles the data packet
3. Sends the packet to the device
4. Waits for a response

The response from the device causes the MAC to send a status update to the AIU.

For IN or PING transactions, the MAC waits for the data or handshake response from the device. For data responses, the MAC performs the following steps:

1. Validates the data
2. Writes the data to the receive FIFO buffer
3. Sends a status update to the AIU
4. Sends a handshake to the device, if appropriate

19.4.1.6.2. Host Protocol

In host mode, the MAC performs the following functions:

- Detects connect, disconnect, and remote wakeup events on the USB link
- Initiates reset
- Initiates speed enumeration processes
- Generates Start of Frame (SOF) packets.

19.4.1.6.3. Device Protocol

In device mode, the MAC performs the following functions:

- Handles USB reset sequence
- Handles speed enumeration
- Detects USB suspend and resume activity on the USB link
- Initiates remote wakeup
- Decodes SOF packets

19.4.1.6.4. OTG Protocol

The MAC handles HNP and SRP for OTG operation. HNP provides a mechanism for swapping host and device roles. SRP provides mechanisms for the host to turn off V_{BUS} to save power, and for a device to request a new USB session.

19.4.1.7. Wakeup and Power Control

To reduce power, the USB OTG controller supports a power-down mode. In power-down mode, the controller and the PHY can shut down their clocks. The controller supports wakeup on the detection of the following events:

- Resume
- Remote wakeup
- Session request protocol
- New session start

19.4.1.8. PHY Interface Unit

The USB OTG controller supports synchronous SDR data transmission to a ULPI PHY. The SDR mode implements an eight-bit data bus.

19.4.1.9. DMA

The DMA has two modes of operation. You program your software to select between scatter-gather DMA mode or buffer DMA mode depending on the controllers function.

If the controller is functioning as a generic root hub, you should program your software to select the buffer DMA mode that supports split transfers.

If generic root hub functionality is not required, or if the controller is configured in Device mode, you can program your software to select scatter-gather DMA mode.

If you wish to dynamically switch the mode of operation based on the queried device status or capability, your software driver must cleanly switch between the two modes of operation. For example, you may want the controller to default to scatter-gather DMA mode and only change mode when it detects a generic HUB with fast-speed and low-speed capability. Some basic requirements for switching include:

- A soft reset must be issued before changing modes.
- If buffer DMA mode is selected, then the Host mode periodic request queue depth must not be set to 16.
- Devices must be re-enumerated.

19.4.2. Local Memory Buffer

The NAND flash controller has three local SRAM memory buffers.

- The write FIFO buffer is a 128 × 32-bit memory (512 total bytes)
- The read FIFO buffer is a 32 × 32-bit memory (128 total bytes)
- The ECC buffer is a 96 × 16-bit memory (1536 total bytes)

The SPRAM is a 8192 × 35-bit (32 data bits and 3 control bits) memory and includes support for ECC (Error Checking and Correction). The ECC block is integrated around a memory wrapper. It provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected) and when double-bit uncorrectable errors are detected. The ECC logic also allows the injection of single- and double-bit errors for test purposes. The ECC feature is disabled by default. It must be initialized to enable the ECC function.

19.4.3. Clocks

Table 237. USB OTG Controller Clock Inputs

All clocks must be operational when reset is released. No special handling is required on the clocks.

Clock Signal	Frequency	Functional Usage
usb_mp_clk	60 – 200 MHz	Drives the master and slave interfaces, DMA controller, and internal FIFO buffers
usb0_ulpi_clk	60 MHz	ULPI reference clock for usb0 from external ULPI PHY I/O pin
usb1_ulpi_clk	60 MHz	ULPI reference clock for usb1 from external ULPI PHY I/O pin

19.4.3.1. Clock Gating

You can clock gate the `ulpi_clk` through software. By programming the `usbclken` bit of the `en` register in the `perpllgrp` you can enable or disable the `ulpi_clk` to the USB.

Related Information

[Clock Manager Address Map and Register Definitions](#) on page 71

19.4.4. Resets

The USB OTG controller can be reset either through the hardware reset input or through software.

19.4.4.1. Reset Requirements

There must be a minimum of 12 cycles on the `ulpi_clk` clock before the controller is taken out of reset. During reset, the USB OTG controller asserts the `ulpi_stp` signal. The PHY outputs a clock when it sees the `ulpi_stp` signal asserted. However, if the pin multiplexers are not programmed, the PHY does not see the `ulpi_stp` signal. As a result, the `ulpi_clk` clock signal does not arrive at the USB OTG controller.

Software must ensure that the reset is active for a minimum of two `usb_mp_clk` cycles. There is no maximum assertion time.

19.4.4.2. Hardware Reset

Each of the USB OTG controllers has one reset input from the reset manager. The reset signal is asserted during a cold or warm reset event. The reset manager holds the controllers in reset until software releases the resets. Software releases resets by clearing the appropriate USB bits in the Peripheral Module Reset Register (`permodrst`) in the HPS reset manager.

The reset input resets the following blocks:

- The master and slave interface logic
- The integrated DMA controller
- The internal FIFO buffers
- The CSR

The reset input is synchronized to the `usb_mp_clk` domain. The reset input is also synchronized to the ULPI clock within the USB OTG controller and is used to reset the ULPI PHY domain logic.

19.4.4.3. Software Reset

Software can reset the controller by setting the Core Soft Reset (`csftrst`) bit in the Reset Register (`grstctl`) in the Global Registers (`globgrp`) group of the USB OTG controller.

Software resets are useful in the following situations:

- A PHY selection bit is changed by software. Resetting the USB OTG controller is part of clean-up to ensure that the PHY can operate with the new configuration or clock.
- During software development and debugging.

19.4.4.4. Taking the USB 2.0 OTG Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

19.4.5. Interrupts

Table 238. USB OTG Interrupt Conditions

Each USB OTG controller has a single interrupt output. Interrupts are asserted on the conditions shown in the following table.

Condition	Mode
Device-initiated remote wakeup is detected.	Host mode
Session request is detected from the device.	Host mode
Device disconnect is detected.	Host mode
Host periodic TX FIFO buffer is empty (can be further programmed to indicate half-empty).	Host mode
<i>continued...</i>	

Condition	Mode
Host channels interrupt received.	Host mode
Incomplete periodic transfer is pending at the end of the microframe.	Host mode
Host port status interrupt received.	Host mode
External host initiated resume is detected.	Device mode
Reset is detected when in suspend or normal mode.	Device mode
USB suspend mode is detected.	Device mode
Data fetch is suspended due to TX FIFO buffer full or request queue full.	Device mode
At least one isochronous OUT endpoint is pending at the end of the microframe.	Device mode
At least one isochronous IN endpoint is pending at the end of the microframe.	Device mode
At least one IN or OUT endpoint interrupt is pending at the end of the microframe.	Device mode
The end of the periodic frame is reached.	Device mode
Failure to write an isochronous OUT packet to the RX FIFO buffer. The RX FIFO buffer does not have enough space to accommodate the maximum packet size for the isochronous OUT endpoint.	Device mode
Enumeration has completed.	Device mode
Connector ID change.	Common modes
Mode mismatch. Software accesses registers belonging to an incorrect mode.	Common modes
Nonperiodic TX FIFO buffer is empty.	Common modes
RX FIFO buffer is not empty.	Common modes
Start of microframe.	Common modes
Device connection debounce is complete in host mode.	OTG interrupts
A-Device timeout while waiting for B-Device connection.	OTG interrupts
Host negotiation is complete.	OTG interrupts
Session request is complete.	OTG interrupts
Session end is detected in device mode.	OTG interrupts

19.5. USB OTG Controller Programming Model

For detailed information about using the USB OTG controller, consult your operating system (OS) driver documentation. The OS vendor provides application programming interfaces (APIs) to control USB host, device and OTG operation. This section provides a brief overview of the following software operations:

- Enabling SPRAM ECCs
- Host operation
- Device operation

19.5.1. Enabling SPRAM ECCs

The L3 interconnect has access to the SPRAM and is accessible through the USB OTG L3 slave interface. Software accesses the SPRAM through the `directfifo` memory space, in the USB OTG controller address space.

To enable the ECC feature, refer to the ECC chapter in the *Arria 10 Hard Processor System Technical Reference Manual*.

Note: Software cannot access the SPRAM beyond the 32-KB range. Out-of-range read transactions return indeterminate data. Out-of-range write transactions are ignored.

Related Information

[Error Checking and Correction Controller](#) on page 1086

19.5.2. Host Operation

19.5.2.1. Host Initialization

After power up, the USB port is in its default mode. No VBUS is applied to the USB cable. The following process sets up the USB OTG controller as a USB host.

1. To enable power to the USB port, the software driver sets the Port Power (`prtpwr`) bit to 1 in the Host Port Control and Status Register (`hpert`) of the Host Mode Registers (`hostgrp`) group. This action drives the V_{BUS} signal on the USB link.

The controller waits for a connection to be detected on the USB link.

2. When a USB device connects, an interrupt is generated. The Port Connect Detected (`PrtConnDet`) bit in `hpert` is set to 1.
3. Upon detecting a port connection, the software driver initiates a port reset by setting the Port Reset (`prtrst`) bit to 1 in `hpert`.
4. The software driver must wait a minimum of 10 ms so that speed enumeration can complete on the USB link.
5. After the 10 ms, the software driver sets `prtrst` back to 0 to release the port reset.
6. The USB OTG controller generates an interrupt. The Port Enable Disable Change (`prtenchn`) and Port Speed (`prtspd`) bits, in `hpert`, are set to reflect the enumerated speed of the device that attached.

At this point the port is enabled for communication. Keep alive or SOF packets are sent on the port. If a USB 2.0-capable device fails to initialize correctly, it is reported as a USB 1.1 device.

The Host Frame Interval Register (`hfir`) is updated with the corresponding PHY clock settings. The `hfir`, used for sending SOF packets, is in the Host Mode Registers (`hostgrp`) group.

7. The software driver must program the following registers in the Global Registers (`globgrp`) group, in the order listed:

- a. Receive FIFO Size Register (`grxfsize`)—selects the size of the receive FIFO buffer
 - b. Non-periodic Transmit FIFO Size Register (`gnptxfsize`)—selects the size and the start address of the non-periodic transmit FIFO buffer for nonperiodic transactions
 - c. Host Periodic Transmit FIFO Size Register (`hptxfsize`)—selects the size and start address of the periodic transmit FIFO buffer for periodic transactions
8. System software initializes and enables at least one channel to communicate with the USB device.

19.5.2.2. Host Transaction

When configured as a host, the USB OTG controller pipes the USB transactions through one of two request queues (one for periodic transactions and one for nonperiodic transactions). Each entry in the request queue holds the SETUP, IN, or OUT channel number along with other information required to perform a transaction on the USB link. The sequence in which the requests are written to the queue determines the sequence of transactions on the USB link.

The host processes the requests in the following order at the beginning of each frame or microframe:

1. Periodic request queue, including isochronous and interrupt transactions
2. Nonperiodic request queue (bulk or control transfers)

The host schedules transactions for each enabled channel in round-robin fashion. When the host controller completes the transfer for a channel, the controller updates the DMA descriptor status in the system memory.

For OUT transactions, the host controller uses two transmit FIFO buffers to hold the packet payload to be transmitted. One transmit FIFO buffer is used for all nonperiodic OUT transactions and the other is used for all periodic OUT transactions.

For IN transactions, the USB host controller uses one receive FIFO buffer for all periodic and nonperiodic transactions. The controller holds the packet payload from the USB device in the receive FIFO buffer until the packet is transferred to the system memory. The receive FIFO buffer also holds the status of each packet received. The status entry holds the IN channel number along with other information, including received byte count and validity status.

For generic hub operations, the USB OTG controller uses SPLIT transfers to communicate with slower-speed devices downstream of the hub. For these transfers, the transaction accumulation or buffering is performed in the generic hub, and is scheduled accordingly. The USB OTG controller ensures that enough transmit and receive buffers are allocated when the downstream transactions are completed or when accumulated data is ready to be sent upstream.

19.5.3. Device Operation

19.5.3.1. Device Initialization

The following process sets up the USB OTG controller as a USB device:

1. After power up, the USB OTG controller must be set to the desired device speed by writing to the Device Speed (`devspd`) bits in the Device Configuration Register (`dcfg`) in the Device Mode Registers (`devgrp`) group. After the device speed is set, the controller waits for a USB host to detect the USB port as a device port.
2. When an external host detects the USB port, the host performs a port reset, which generates an interrupt to the USB device software. The USB Reset (`usbrst`) bit in the Interrupt (`port reset`) register in the Global Registers (`globgrp`) group is set. The device software then sets up the data FIFO buffer to receive a SETUP packet from the external host. Endpoint 0 is not enabled yet.
3. After completion of the port reset, the operation speed required by the external host is known. Software reads the device speed status and sets up all the remaining required transaction fields to enable control endpoint 0.

After completion of this process, the device is receiving SOF packets, and is ready for the USB host to set up the device's control endpoint.

19.5.3.2. Device Transaction

When configured as a device, the USB OTG controller uses a single FIFO buffer to receive the data for all the OUT endpoints. The receive FIFO buffer holds the status of the received data packet, including the byte count, the data packet ID (PID), and the validity of the received data. The DMA controller reads the data out of the FIFO buffer as the data are received. If a FIFO buffer overflow condition occurs, the controller responds to the OUT packet with a NAK, and internally rewinds the pointers.

For IN endpoints, the controller uses dedicated transmit buffers for each endpoint. The application does not need to predict the order in which the USB host will access the nonperiodic endpoints. If a FIFO buffer underrun condition occurs during transmit, the controller inverts the cyclic redundancy code (CRC) to mark the packet as corrupt on the USB link.

The application handles one data packet at a time per endpoint in transaction-level operations. The software receives an interrupt on completion of every packet. Based on the handshake response received on the USB link, the application determines whether to retry the transaction or proceed with the next transaction, until all packets in the transfer are completed.

19.5.3.2.1. IN Transactions

For an IN transaction, the application performs the following steps:

1. Enables the endpoint
2. Triggers the DMA engine to write the associated data packet to the corresponding transmit FIFO buffer
3. Waits for the packet completion interrupt from the controller

When an IN token is received on an endpoint when the associated transmit FIFO buffer does not contain sufficient data, the controller performs the following steps:

1. Generates an interrupt
2. Returns a NAK handshake to the USB host

If sufficient data is available, the controller transmits the data to the USB host.

19.5.3.2.2. OUT Transactions

For an OUT transaction, the application performs the following steps:

1. Enables the endpoint
2. Waits for the packet received interrupt from the USB OTG controller
3. Retrieves the packet from the receive FIFO buffer

When an OUT token or PING token is received on an endpoint where the receive FIFO buffer does not have sufficient space, the controller performs the following steps:

1. Generates an interrupt
2. Returns a NAK handshake to USB host

If sufficient space is available, the controller stores the data in the receive FIFO buffer and returns an ACK handshake to the USB link.

19.5.3.2.3. Control Transfers

For control transfers, the application performs the following steps:

1. Waits for the packet received interrupt from the controller
2. Retrieves the packet from the receive buffer

Because the control transfer is governed by USB protocol, the controller always responds with an ACK handshake.

19.6. USB 2.0 OTG Controller Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the [Arria 10 HPS Address Map and Register Definitions](#).

19.6.1.2. gotgctl

OTG Control and Status Register

Module Instance	Base Address	Register Address
i_usbotg_0_globgrp	0xFFB00000	0xFFB00000
i_usbotg_1_globgrp	0xFFB40000	0xFFB40000

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

gotgctl Fields

Bit	Name	Description	Access	Reset						
21	curmod	Mode: Host and Device Current Mode of Operation (CurMod) Indicates the current mode. 1'b0: Device mode 1'b1: Host mode	RO	0x0						
20	otgver	OTG Version (OTGVer) Indicates the OTG revision. 1'b0: OTG Version 1.3. In this version the core supports Data line pulsing and VBus pulsing for SRP. 1'b1: OTG Version 2.0. In this version the core supports only Data line pulsing for SRP. <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>VER13</td></tr><tr><td>0x1</td><td>VER20</td></tr></table>	Value	Description	0x0	VER13	0x1	VER20	RW	0x0
Value	Description									
0x0	VER13									
0x1	VER20									
19	bsesvld	Mode: Device only B-Session Valid (BSesVld) Indicates the Device mode transceiver status. 1'b0: B-session is not valid. 1'b1: B-session is valid. In OTG mode, you can use this bit to determine IF the device is connected or disconnected. Note: If you do not enabled OTG features (such as SRP and HNP), the read reset value will be 1.The vbus assigns the values internally for non-SRP or non-HNP configurations. <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>NOTVALID</td></tr><tr><td>0x1</td><td>VALID</td></tr></table>	Value	Description	0x0	NOTVALID	0x1	VALID	RO	0x0
Value	Description									
0x0	NOTVALID									
0x1	VALID									
18	asesvld	Mode: Host only A-Session Valid (ASesVld) Indicates the Host mode transceiver status. 1'b0: A-session is not valid 1'b1: A-session is valid Note: If you do not enabled OTG features (such as SRP and HNP), the read reset value will be 1.The vbus assigns the values internally for non-SRP or non-HNP configurations. <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>VALID</td></tr><tr><td>0x1</td><td>NOTVALID</td></tr></table>	Value	Description	0x0	VALID	0x1	NOTVALID	RO	0x0
Value	Description									
0x0	VALID									
0x1	NOTVALID

Bit	Name	Description	Access	Reset						
		burst type. Enable this feature when the AHB Slave connected to the DWC_otg core does not support INCR burst (and when Split, and Retry transactions are not being used in the bus).								
22	notialldmawrit	<p>Notify All Dma Write Transactions (NotiAllDmaWrit) This bit is programmed to enable the System DMA Done functionality for all the DMA write Transactions corresponding to the Channel/Endpoint. This bit is valid only when GAHBCFG.RemMemSupp is set to 1. GAHBCFG.NotiAllDmaWrit = 1 - HSOTG core asserts int_dma_req for all the DMA write transactions on the AHB interface along with int_dma_done, chep_last_transact and chep_number signal informations. The core waits for sys_dma_done signal for all the DMA write transactions in order to complete the transfer of a particular Channel/Endpoint. GAHBCFG.NotiAllDmaWrit = 0 - HSOTG core asserts int_dma_req signal only for the last transaction of DMA write transfer corresponding to a particular Channel/Endpoint. Similarly, the core waits for sys_dma_done signal only for that transaction of DMA write to complete the transfer of a particular Channel/Endpoint.</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>LASTTRANS</td></tr><tr><td>0x1</td><td>ALLTRANS</td></tr></table>	Value	Description	0x0	LASTTRANS	0x1	ALLTRANS	RW	0x0
Value	Description									
0x0	LASTTRANS									
0x1	ALLTRANS									
21	remmemsupp	<p>Remote Memory Support (RemMemSupp) This bit is programmed to enable the functionality to wait for the system DMA Done Signal for the DMA Write Transfers. GAHBCFG.RemMemSupp=1 - The int_dma_req output signal is asserted when HSOTG DMA starts write transfer to the external memory. When the core is done with the Transfers it asserts int_dma_done signal to flag the completion of DMA writes from HSOTG. The core then waits for sys_dma_done signal from the system to proceed further and complete the Data Transfer corresponding to a particular Channel/Endpoint. GAHBCFG.RemMemSupp=0 - The int_dma_req and int_dma_done signals are not asserted and the core proceeds with the assertion of the XferComp interrupt as soon as the DMA write transfer is done at the HSOTG Core Boundary and it doesn't wait for the sys_dma_done signal to complete the DATA transfers</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>DISABLED</td></tr></table>	Value	Description	0x0	DISABLED	RW	0x0

		<p>All module state machines (except the AHB Slave Unit) are reset to the IDLE state, and all the transmit FIFOs and the receive FIFO are flushed.</p> <p>Any transactions on the AHB Master are terminated as soon as possible, after gracefully completing the last data phase of an AHB transfer. Any transactions on the USB are terminated immediately.</p> <p>When Hibernation or ADP feature is enabled, the PMU module is not reset by the Core Soft Reset.</p> <p>The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit is cleared software must wait at least 3 PHY clocks before doing any access to the PHY domain (synchronization delay). Software must also must check that bit 31 of this register is 1 (AHB Master is IDLE) before starting any operation. Typically software reset is used during software development and also when you dynamically change the PHY selection bits in the USB configuration registers listed above. When you change the PHY, the corresponding clock For the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper operation.</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>NOTACTIVE</td></tr><tr><td>0x1</td><td>ACTIVE</td></tr></table>	Value	Description	0x0	NOTACTIVE	0x1	ACTIVE

22	fetsusp	<div>Mode: Device only Data Fetch Suspended (FetSusp) This interrupt is valid only in DMA mode. This interrupt indicates that the core has stopped fetching data For IN endpoints due to the unavailability of TxFIFO space or Request Queue space. This interrupt is used by the application For an endpoint mismatch algorithm. For example, after detecting an endpoint mismatch, the application: Sets a Global non-periodic IN NAK handshake Disables In endpoints Flushes the FIFO Determines the token sequence from the IN Token Sequence Learning Queue Re-enables the endpoints Clears the Global non-periodic IN NAK handshake If the Global non-periodic IN NAK is cleared, the core has not yet fetched data For the IN endpoint, and the IN token is received: the core generates an 'IN token received when FIFO empty' interrupt. The OTG Then sends the host a NAK response. To avoid this scenario, the application can check the GINTSTS.FetSusp interrupt, which ensures that the FIFO is full before clearing a Global NAK handshake. Alternatively, the application can mask the "IN token received when FIFO empty" interrupt when clearing a Global IN NAK handshake.</div>	RW	0x0

Host Configuration Register

Module Instance	Base Address	Register Address
i_usbotg_0_hostgrp	0xFFB00400	0xFFB00400
i_usbotg_1_hostgrp	0xFFB40400	0xFFB40400

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

The width of this counter is specified as Width of Packet Counters</p>	RW	0x0				
18:0	xfersize	<p>Transfer Size (XferSize) For an OUT, this field is the number of data bytes the host sends during the transfer. For an IN, this field is the buffer size that the application has Reserved For the transfer. The application is expected to program this field as an integer multiple of the maximum packet size For IN transactions (periodic and non-periodic). The width of this counter is specified as Width of Transfer Size Counters</p>	RW	0x0

Bit	Name	Description	Access	Reset				
		<table><tr><th>Value</th><th>Description</th></tr><tr><td>0x3</td><td>MDATA</td></tr></table>	Value	Description	0x3	MDATA		
Value	Description							
0x3	MDATA							
28:19	pktcnt	<p>Packet Count (PktCnt) This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as Width of Packet Counters</p>	RW	0x0				
18:0	xfersize	<p>Transfer Size (XferSize) For an OUT, this field is the number of data bytes the host sends during the transfer. For an IN, this field is the buffer size that the application has Reserved For the transfer. The application is expected to program this field as an integer multiple of the maximum packet size For IN transactions (periodic and non-periodic). The width of this counter is specified as Width of Transfer Size Counters</p>	RW	0x0

Need to be set to zero by application.		

19.6.2.121. hcdmab15

Host Channel 15 DMA Buffer Address Register

Module Instance	Base Address	Register Address
i_usbotg_0_hostgrp	0xFFB00400	0xFFB006FC
i_usbotg_1_hostgrp	0xFFB40400	0xFFB406FC

Offset: 0x2FC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

19.6.3.2. dcfg

Device Configuration Register

Module Instance	Base Address	Register Address
i_usbotg_0_devgrp	0xFFB00800	0xFFB00800
i_usbotg_1_devgrp	0xFFB40800	0xFFB40800

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

dcfg Fields

Bit	Name	Description	Access	Reset
31:26	resvalid	Resume Validation Period (ResValid) This field is effective only when DCFG.Ena32KHzSusp is set. It will control the resume period when the core resumes from suspend. The core counts for "ResValid" number of clock cycles to detect a valid resume when this is set	RW	0x2
25:24	perschintvl	Periodic Scheduling Interval (PerSchIntvl) PerSchIntvl must be programmed only For Scatter/Gather DMA mode. Description: This field specifies the amount of time the Internal DMA engine must allocate For fetching periodic IN endpoint data. Based on the number of periodic endpoints, this value must be specified as 25,50 or 75% of (micro)frame. When any periodic endpoints are active, the internal DMA engine allocates the specified amount of time in fetching periodic IN endpoint data When no periodic endpoints are active, Then the internal DMA engine services non-periodic endpoints, ignoring this field.	RW	0x0
continued...				

Bit	Name	Description	Access	Reset										
		<p>After the specified time within a (micro)frame, the DMA switches to fetching For non-periodic endpoints. 2'b00: 25% of (micro)frame. 2'b01: 50% of (micro)frame. 2'b10: 75% of (micro)frame. 2'b11: Reserved. dctl Fields

Bit	Name	Description	Access	Reset						
17	encontonbna	<p>Enable Continue on BNA (EnContOnBNA) This bit enables the DWC_otg core to continue on BNA for Bulk OUT endpoints. With this feature enabled, when a Bulk OUT endpoint receives a BNA interrupt the core starts processing the descriptor that caused the BNA interrupt after the endpoint re-enables the endpoint. 1'b0: After receiving BNA interrupt,the core disables the endpoint. When the endpoint is re-enabled by the application,the core starts processing from the DOEPDMA descriptor. 1'b1: After receiving BNA interrupt, the core disables the endpoint. When the endpoint is re-enabled by the application, the core starts processing from the descriptor that received the BNA interrupt. This bit is valid only when OTG_EN_DESC_DMA == 1'b1. It is a one-time programmable after reset bit like any other DCTL register bits.</p>	RW	0x0						
16	nakonbble	<p>NAK on Babble Error (NakOnBble) Set NAK automatically on babble (NakOnBble). The core sets NAK automatically for the endpoint on which babble is received.</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>DISABLED</td></tr><tr><td>0x1</td><td>ENABLED</td></tr></table>	Value	Description	0x0	DISABLED	0x1	ENABLED	RW	0x0
Value	Description									
0x0	DISABLED									
0x1	ENABLED									
15	ignrfrmnum	<p>Ignore Frame number For Isochronous End points (IgnrFrmNum) Do NOT program IgnrFrmNum bit to 1'b1 when the core is operating in threshold mode. Note: When Scatter/Gather DMA mode is enabled this feature is not applicable to High Speed, High bandwidth transfers. When this bit is enabled, there must be only one packet per descriptor. 0: The core transmits the packets only in the frame number in which they are intended to be transmitted. 1: The core ignores the frame number, sending packets immediately as the packets are ready. In Scatter/Gather DMA mode, if this bit is enabled, the packets are not flushed when a ISOC IN token is received</p>	RW	0x0

Bit	Name	Description	Access	Reset						
27	arbprken	<p>Arbiter Parking Enable (ArbPrkEn) This bit controls internal DMA arbiter parking For IN endpoints. When thresholding is enabled and this bit is Set to one, Then the arbiter parks on the IN endpoint For which there is a token received on the USB. This is done to avoid getting into underrun conditions. By Default the parking is enabled.</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>DISABLED</td></tr><tr><td>0x1</td><td>ENABLED</td></tr></table>	Value	Description	0x0	DISABLED	0x1	ENABLED	RW	0x1
Value	Description									
0x0	DISABLED									
0x1	ENABLED									
25:1 7	rxthrlen	<p>Receive Threshold Length (RxThrLen) This field specifies Receive thresholding size in DWORDS. This field also specifies the amount of data received on the USB before the core can start transmitting on the AHB. The threshold length has to be at least eight DWORDS. The recommended value For ThrLen is to be the same as the programmed AHB Burst Length (GAHB_CFG.HBstLen).</p>	RW	0x8						
16	rxthren	<p>Receive Threshold Enable (RxThrEn) When this bit is Set, the core enables thresholding in the receive direction. Note: We recommends that you do not enable RxThrEn, because it may cause issues in the RxFIFO especially during error conditions such as RxError and Babble.</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>DISABLED</td></tr><tr><td>0x1</td><td>ENABLED</td></tr></table>	Value	Description	0x0	DISABLED	0x1	ENABLED	RW	0x0
Value	Description									
0x0	DISABLED									
0x1	ENABLED									
12:1 1	ahbthrratio	<p>AHB Threshold Ratio (AHBThrRatio) These bits define the ratio between the AHB threshold and the MAC threshold for the transmit path only. The AHB threshold always remains less than or equal to the USB threshold, because this does not increase overhead. Both the AHB and the MAC threshold must be DWORD-aligned. The application needs to program TxThrLen and the AHBThrRatio to make the AHB Threshold value DWORD aligned. If the AHB threshold value is not DWORD aligned, the core might not behave correctly. When programming the TxThrLen and AHBThrRatio, the application must ensure that the minimum AHB threshold value does not go below 8 DWORDS to meet the USB turnaround time requirements. 2'b00: AHB threshold = MAC threshold 2'b01: AHB threshold = MAC threshold / 2 2'b10: AHB threshold = MAC threshold / 4 2'b11: AHB threshold = MAC threshold / 8</p>	RW	0x0

dieptsiz0 Fields

Bit	Name	Description	Access	Reset
20:1 9	pktcnt	Packet Count (PktCnt) Indicates the total number of USB packets that constitute the Transfer Size amount of data For endpoint 0. In Endpoints : This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO. OUT Endpoints: This field is decremented every time a packet (maximum size or short packet) is written to the RxFIFO.	RW	0x0
6:0	xfersize	Transfer Size (XferSize) This field contains the transfer size in bytes for the current endpoint. The transfer size (XferSize) = Sum of buffer sizes across all descriptors in the list for the endpoint. In Buffer DMA, the core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. IN Endpoints: The core decrements this field every time a packet from the external memory is written to the TxFIFO. OUT Endpoints: The core decrements this field every time a packet is read from the RxFIFO and written to the external memory.	RW	0x0

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

dieptsiz7 Fields

Bit	Name	Description	Access	Reset								
30:29	mc	<p>Applies to IN endpoints only. For periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. 2'b01: 1 packet 2'b10: 2 packets 2'b11: 3 packets For non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetch for an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp)</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x1</td><td>PACKETONE</td></tr><tr><td>0x2</td><td>PACKETTWO</td></tr><tr><td>0x3</td><td>PACKETTHREE</td></tr></table>	Value	Description	0x1	PACKETONE	0x2	PACKETTWO	0x3	PACKETTHREE	RW	0x0
Value	Description											
0x1	PACKETONE											
0x2	PACKETTWO											
0x3	PACKETTHREE											
28:19	pktcnt	<p>Packet Count (PktCnt) Indicates the total number of USB packets that constitute the Transfer Size amount of data For endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.</p>	RW	0x0								
18:0	xfersize	<p>Transfer Size (XferSize) Indicates the transfer size in bytes For endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.</p>	RW	0x0
