Contents

1. Intel® Arria® 10 Hard Processor System Technical Reference Manual Revision History.....	17
2. Introduction to the Hard Processor System.....	32
2.1. Features of the HPS.....	35
2.2. HPS Block Diagram and System Integration.....	36
2.2.1. HPS Block Diagram.....	36
2.2.2. Cortex-A9 MPCore.....	37
2.2.3. HPS Interfaces.....	37
2.2.4. System Interconnect.....	38
2.2.5. On-Chip Memory.....	39
2.2.6. Flash Memory Controllers.....	40
2.2.7. Support Peripherals.....	42
2.2.8. Interface Peripherals.....	45
2.2.9. CoreSight Debug and Trace.....	48
2.2.10. Hard Processor System I/O Pin Multiplexing.....	49
2.3. Endian Support.....	49
2.4. Introduction to the Hard Processor System Address Map.....	50
2.4.1. HPS Address Spaces.....	50
2.4.2. HPS Peripheral Region Address Map.....	52
3. Clock Manager.....	56
3.1. Features of the Clock Manager.....	56
3.2. Clock Manager Block Diagram and System Integration.....	58
3.2.1. L4 Peripheral Clocks.....	59
3.2.2. Boot Clock.....	60
3.3. Functional Description of the Clock Manager.....	61
3.3.1. Clock Manager Building Blocks.....	61
3.3.2. PLL Integration.....	63
3.3.3. Hardware-Managed and Software-Managed Clocks.....	65
3.3.4. Hardware Sequenced Clock Groups.....	65
3.3.5. Software Sequenced Clocks.....	67
3.3.6. Resets.....	69
3.3.7. Security.....	70
3.3.8. Interrupts.....	71
3.4. Clock Manager Address Map and Register Definitions.....	71
3.4.1. clkmgr_clkmgrp Address Map.....	71
3.4.2. clkmgr_mainpllgrp Address Map.....	86
3.4.3. clkmgr_perpllgrp Address Map.....	110
3.4.4. clkmgr_alteragrp Address Map.....	135
4. Reset Manager.....	138
4.1. Reset Manager Block Diagram and System Integration.....	140
4.1.1. Reset Controller.....	141
4.1.2. Security Reset Functions.....	144
4.1.3. Module Reset Signals.....	144
4.1.4. Slave Interface and Status Register.....	149
4.2. Functional Description of the Reset Manager.....	150

4.2.1. Reset Sequencing.....	151
4.2.2. Reset Pins.....	155
4.2.3. Reset Effects.....	156
4.2.4. Reset Handshaking.....	156
4.3. Reset Manager Address Map and Register Definitions.....	157
4.3.1. rst_mgr Address Map.....	157
5. FPGA Manager.....	202
5.1. Features of the FPGA Manager.....	202
5.2. FPGA Manager Block Diagram and System Integration.....	203
5.3. Functional Description of the FPGA Manager.....	204
5.3.1. FPGA Configuration.....	204
5.3.2. FPGA Status.....	205
5.3.3. Error Message Extraction.....	205
5.3.4. Data AES Decryption.....	205
5.3.5. Boot Handshake.....	205
5.3.6. General Purpose I/O.....	206
5.3.7. Clock.....	206
5.3.8. Reset.....	206
5.4. FPGA Manager Address Map and Register Definitions.....	206
5.4.1. fpga_mgr_fpgamgrdata Address Map.....	207
5.4.2. fpga_mgr_fpgamgrregs Address Map.....	208
6. System Manager.....	244
6.1. Features of the System Manager.....	244
6.2. System Manager Block Diagram and System Integration.....	245
6.3. Functional Description of the System Manager.....	246
6.3.1. Boot Configuration and System Information.....	246
6.3.2. Additional Module Control.....	247
6.3.3. Boot ROM Code.....	249
6.3.4. FPGA Interface Enables.....	250
6.3.5. ECC and Parity Control.....	251
6.3.6. Preloader Handoff Information.....	252
6.3.7. Clocks.....	252
6.3.8. Resets.....	252
6.4. System Manager Address Map and Register Definitions.....	252
6.4.1. sys_mgr_core Address Map.....	252
6.4.2. sys_mgr_rom Address Map.....	317
7. SoC Security.....	332
7.1. Security Manager.....	333
7.1.1. Security Manager Block Diagram.....	334
7.1.2. Functional Overview.....	335
7.1.3. Functional Description.....	335
7.2. Security System Extensions.....	350
7.2.1. TrustZone.....	350
7.2.2. Arria 10 HPS Secure Firewalls.....	353
8. System Interconnect.....	364
8.1. About the System Interconnect.....	365
8.1.1. Features of the System Interconnect.....	365
8.1.2. Block Diagram and System Integration.....	365

8.1.3. Arria 10 HPS Secure Firewalls.....	370
8.1.4. About the Rate Adapters.....	371
8.1.5. About the SDRAM L3 Interconnect.....	371
8.1.6. About Arbitration and Quality of Service	374
8.1.7. About the Service Network.....	374
8.1.8. About the Observation Network.....	375
8.2. Functional Description of the System Interconnect.....	375
8.2.1. System Interconnect Address Spaces.....	377
8.2.2. Secure Transaction Protection.....	384
8.2.3. System Interconnect Master Properties.....	384
8.2.4. System Interconnect Slave Properties.....	386
8.2.5. System Interconnect Clocks.....	387
8.2.6. System Interconnect Resets.....	388
8.2.7. Functional Description of the Rate Adapters.....	389
8.2.8. Functional Description of the Firewalls.....	389
8.2.9. Functional Description of the SDRAM L3 Interconnect.....	391
8.2.10. Functional Description of the Arbitration Logic.....	396
8.2.11. Functional Description of the QoS Generators.....	396
8.2.12. Functional Description of the Observation Network.....	400
8.3. Configuring the System Interconnect.....	402
8.3.1. Configuring the Rate Adapters.....	402
8.3.2. Configuring the SDRAM Scheduler.....	403
8.3.3. Configuring the Hard Memory Controller.....	404
8.3.4. Configuring the Quality of Service Logic.....	405
8.4. System Interconnect Address Map and Register Definitions.....	411
8.4.1. ecc_hmc_ocp_slv_block Address Map.....	411
8.4.2. noc_l4_priv_l4_priv_filter Address Map.....	459
8.4.3. noc_mpu_m0_MPU_M1toDDRResp_main_RateAdapter Address Map.....	470
8.4.4. noc_mpu_m0_MPU_M0_rate_adResp_main_RateAdapter Address Map.....	474
8.4.5. noc_mpu_m0_L4_MP_rate_ad_main_RateAdapter Address Map.....	478
8.4.6. noc_mpu_m0_fpga2soc_rate_ad_main_RateAdapter Address Map.....	482
8.4.7. noc_mpu_m0_L3Tosoc2fpgaResp_main_RateAdapter Address Map.....	486
8.4.8. noc_mpu_m0_acp_rate_ad_main_RateAdapter Address Map.....	490
8.4.9. noc_mpu_m0_ddr_T_main_Probe Address Map.....	494
8.4.10. noc_mpu_m0_ddr_T_main_Scheduler Address Map.....	550
8.4.11. noc_fw_l4_per_l4_per_scr Address Map.....	559
8.4.12. noc_fw_l4_sys_l4_sys_scr Address Map.....	595
8.4.13. noc_fw_ocram_ocram_scr Address Map.....	639
8.4.14. noc_fw_ddr_mpu_fpga2sdram_ddr_scr Address Map.....	649
8.4.15. noc_fw_ddr_l3_ddr_scr Address Map.....	671
8.4.16. noc_fw_soc2fpga_soc2fpga_scr Address Map.....	684
8.4.17. noc_mpu_m0_Probe_SoC2FPGA_main_Probe Address Map.....	689
8.4.18. noc_mpu_m0_Probe_emacs_main_Probe Address Map.....	738
8.4.19. noc_mpu_m0_Probe_emacs_main_TransactionStatProfiler Address Map.....	788
8.4.20. noc_mpu_m0_cs_obs_at_main_AtEndPoint Address Map.....	798
8.4.21. noc_mpu_m0_cs_obs_at_main_ErrorLogger_0 Address Map.....	803
8.4.22. noc_mpu_m0_Probe_MPU_main_Probe Address Map.....	813
8.4.23. noc_mpu_m0_I_main_QosGenerator Address Map.....	848
8.4.24. noc_mpu_m1_I_main_QosGenerator Address Map.....	855
8.4.25. noc_mpu_fpga2soc_axi32_I_main_QosGenerator Address Map.....	862
8.4.26. noc_mpu_fpga2soc_axi64_I_main_QosGenerator Address Map.....	869

8.4.27. noc_mpu_fpga2soc_axi128_I_main_QosGenerator Address Map.....	876
8.4.28. noc_mpu_dma_I_main_QosGenerator Address Map.....	883
8.4.29. noc_mpu_emac0_m_I_main_QosGenerator Address Map.....	890
8.4.30. noc_mpu_emac1_m_I_main_QosGenerator Address Map.....	897
8.4.31. noc_mpu_emac2_m_I_main_QosGenerator Address Map.....	904
8.4.32. noc_mpu_usb0_m_I_main_QosGenerator Address Map.....	911
8.4.33. noc_mpu_usb1_m_I_main_QosGenerator Address Map.....	918
8.4.34. noc_mpu_nand_m_I_main_QosGenerator Address Map.....	925
8.4.35. noc_mpu_sdmmc_m_I_main_QosGenerator Address Map.....	932
8.4.36. noc_mpu_fpga2sdram0_axi32_I_main_QosGenerator Address Map.....	939
8.4.37. noc_mpu_fpga2sdram0_axi64_I_main_QosGenerator Address Map.....	946
8.4.38. noc_mpu_fpga2sdram0_axi128_I_main_QosGenerator Address Map.....	953
8.4.39. noc_mpu_fpga2sdram1_axi32_I_main_QosGenerator Address Map.....	960
8.4.40. noc_mpu_fpga2sdram1_axi64_I_main_QosGenerator Address Map.....	967
8.4.41. noc_mpu_fpga2sdram2_axi32_I_main_QosGenerator Address Map.....	974
8.4.42. noc_mpu_fpga2sdram2_axi64_I_main_QosGenerator Address Map.....	981
8.4.43. noc_mpu_fpga2sdram2_axi128_I_main_QosGenerator Address Map.....	988
8.4.44. noc_mpu_emac0_m_I_main_TransactionStatFilter Address Map.....	995
9. HPS-FPGA Bridges.....	1007
9.1. Features of the HPS-FPGA Bridges.....	1007
9.2. Arria 10 HPS-FPGA Bridges Block Diagram and System Integration.....	1009
9.3. Functional Description of the HPS-FPGA Bridges.....	1009
9.3.1. Functional Description of the FPGA-to-HPS Bridge.....	1009
9.3.2. Functional Description of the HPS-to-FPGA Bridge.....	1012
9.3.3. Functional Description of the Lightweight HPS-to-FPGA Bridge.....	1015
9.3.4. Clocks and Resets.....	1018
9.3.5. Data Width Sizing.....	1020
9.4. HPS-FPGA Bridges Address Map and Register Definitions for Arria 10.....	1020
9.4.1. fpga_bridge_soc2fpga128 Address Map.....	1020
9.4.2. fpga_bridge_lwsoc2fpga Address Map.....	1021
10. Cortex-A9 Microprocessor Unit Subsystem.....	1022
10.1. Features of the Cortex-A9 MPU Subsystem.....	1022
10.2. Cortex-A9 MPU Subsystem Block Diagram and System Integration.....	1023
10.2.1. Cortex-A9 MPU Subsystem with System Interconnect.....	1023
10.2.2. Cortex-A9 MPU Subsystem Internals.....	1024
10.3. Cortex-A9 MPCore.....	1025
10.3.1. Functional Description.....	1025
10.3.2. Implementation Details.....	1026
10.3.3. Cortex-A9 Processor.....	1026
10.3.4. Interactive Debugging Features.....	1027
10.3.5. L1 Caches.....	1028
10.3.6. Preload Engine.....	1028
10.3.7. Floating Point Unit.....	1029
10.3.8. NEON Multimedia Processing Engine.....	1029
10.3.9. Memory Management Unit.....	1030
10.3.10. Performance Monitoring Unit.....	1033
10.3.11. Arm Cortex-A9 MPCore Timers.....	1033
10.3.12. Generic Interrupt Controller.....	1034
10.3.13. Global Timer.....	1041

10.3.14. Snoop Control Unit.....	1042
10.3.15. Accelerator Coherency Port.....	1043
10.4. L2 Cache.....	1048
10.4.1. Functional Description.....	1048
10.5. CPU Prefetch.....	1054
10.6. TrustZone.....	1055
10.6.1. Secure Partitioning.....	1055
10.6.2. Virtual Processor Operation.....	1056
10.6.3. Secure Debug.....	1057
10.7. Debugging Modules.....	1057
10.7.1. Program Trace.....	1058
10.7.2. Event Trace.....	1058
10.7.3. Cross-Triggering.....	1059
10.8. Clocks.....	1059
10.9. Cortex-A9 MPU Subsystem Register Implementation.....	1059
10.9.1. Cortex-A9 MPU Subsystem Address Map for Arria 10.....	1060
10.9.2. L2 Cache Controller Address Map for Arria 10.....	1061
11. CoreSight Debug and Trace.....	1064
11.1. Features of CoreSight Debug and Trace.....	1065
11.2. Arm CoreSight Documentation.....	1065
11.3. CoreSight Debug and Trace Block Diagram and System Integration.....	1066
11.4. Functional Description of CoreSight Debug and Trace.....	1066
11.4.1. Debug Access Port.....	1066
11.4.2. System Trace Macrocell.....	1068
11.4.3. Trace Funnel.....	1068
11.4.4. CoreSight Trace Memory Controller.....	1069
11.4.5. AMBA Trace Bus Replicator.....	1070
11.4.6. Trace Port Interface Unit.....	1070
11.4.7. Embedded Cross Trigger System.....	1070
11.4.8. Program Trace Macrocell.....	1074
11.4.9. HPS Debug APB Interface.....	1075
11.4.10. FPGA Interface.....	1075
11.4.11. Debug Clocks.....	1077
11.4.12. Debug Resets.....	1078
11.5. CoreSight Debug and Trace Programming Model.....	1079
11.5.1. Coresight Component Address.....	1079
11.5.2. STM Channels.....	1080
11.5.3. CTI Trigger Connections to Outside the Debug System.....	1081
11.5.4. Configuring Embedded Cross-Trigger Connections.....	1083
11.6. CoreSight Debug and Trace Address Map and Register Definitions.....	1084
11.6.1. stm Address Map.....	1084
11.6.2. dap Address Map.....	1085
11.6.3. mpu_regs_MPUSCU Address Map.....	1085
11.6.4. I2_regs_L2DEBUG Address Map.....	1085
12. Error Checking and Correction Controller.....	1086
12.1. ECC Controller Features.....	1086
12.2. ECC Supported Memories.....	1086
12.3. ECC Controller Block Diagram and System Integration.....	1087
12.4. ECC Controller Functional Description.....	1088

12.4.1. Overview.....	1088
12.4.2. ECC Structure.....	1088
12.4.3. Memory Data Initialization.....	1090
12.4.4. Indirect Memory Access.....	1091
12.4.5. Error Logging.....	1096
12.4.6. ECC Controller Interrupts.....	1098
12.4.7. ECC Controller Initialization and Configuration.....	1101
12.4.8. ECC Controller Clocks.....	1102
12.4.9. ECC Controller Reset.....	1103
12.5. ECC Controller Address Map and Register Descriptions.....	1103
12.5.1. emac_rx_ecc Address Map.....	1104
12.5.2. emac_tx_ecc Address Map.....	1145
12.5.3. nandecc_ecc Address Map.....	1186
12.5.4. nandr_ecc Address Map.....	1214
12.5.5. nandw_ecc Address Map.....	1242
12.5.6. sdmmc_ecc Address Map.....	1270
12.5.7. onchip_ram_ecc Address Map.....	1302
12.5.8. dmac_ecc Address Map.....	1330
12.5.9. qspi_ecc Address Map.....	1358
12.5.10. usb_ecc Address Map.....	1386
13. On-Chip Memory.....	1421
13.1. On-Chip RAM.....	1421
13.1.1. Features of the On-Chip RAM.....	1421
13.1.2. On-Chip RAM Block Diagram and System Integration.....	1422
13.1.3. Functional Description of the On-Chip RAM.....	1422
13.2. Boot ROM.....	1424
13.2.1. Features of the Boot ROM.....	1424
13.2.2. Boot ROM Block Diagram and System Integration.....	1425
13.2.3. Functional Description of the Boot ROM.....	1425
13.3. On-Chip Memory Address Map and Register Definitions.....	1426
13.3.1. onchip_ram_ecc Address Map.....	1426
13.3.2. ram_onchip_ram_block Address Map.....	1454
13.3.3. rom_onchip_rom_block Address Map.....	1455
14. NAND Flash Controller.....	1456
14.1. NAND Flash Controller Features.....	1456
14.2. NAND Flash Controller Block Diagram and System Integration.....	1457
14.3. NAND Flash Controller Signal Descriptions.....	1457
14.4. Functional Description of the NAND Flash Controller.....	1458
14.4.1. Discovery and Initialization.....	1458
14.4.2. Bootstrap Interface.....	1459
14.4.3. Configuration by Host.....	1460
14.4.4. Local Memory Buffer.....	1461
14.4.5. Clocks.....	1461
14.4.6. Resets.....	1462
14.4.7. Indexed Addressing.....	1463
14.4.8. Command Mapping.....	1464
14.4.9. Data DMA.....	1469
14.4.10. ECC.....	1473
14.5. NAND Flash Controller Programming Model.....	1476

14.5.1. Basic Flash Programming.....	1477
14.5.2. Flash-Related Special Function Operations.....	1481
14.6. NAND Flash Controller Address Map and Register Definitions.....	1490
14.6.1. nandecc_ecc Address Map.....	1490
14.6.2. nandr_ecc Address Map.....	1518
14.6.3. nandw_ecc Address Map.....	1546
14.6.4. nand_config Address Map.....	1574
14.6.5. nand_param Address Map.....	1618
14.6.6. nand_status Address Map.....	1635
14.6.7. nand_ecc Address Map.....	1665
14.6.8. nand_dma Address Map.....	1668
14.6.9. nand_NANDDATA Address Map.....	1684
15. SD/MMC Controller.....	1685
15.1. Features of the SD/MMC Controller.....	1685
15.1.1. SD Card Support Matrix.....	1687
15.1.2. MMC Support Matrix.....	1687
15.2. SD/MMC Controller Block Diagram and System Integration.....	1688
15.3. SD/MMC Controller Signal Description.....	1688
15.4. Functional Description of the SD/MMC Controller.....	1689
15.4.1. SD/MMC/CE-ATA Protocol.....	1689
15.4.2. BIU.....	1690
15.4.3. CIU.....	1702
15.4.4. Clocks.....	1718
15.4.5. Resets.....	1719
15.4.6. Voltage Switching.....	1720
15.5. SD/MMC Controller Programming Model.....	1722
15.5.1. Software and Hardware Restrictions [†]	1722
15.5.2. Initialization [†]	1724
15.5.3. Controller/DMA/FIFO Buffer Reset Usage.....	1731
15.5.4. Non-Data Transfer Commands.....	1731
15.5.5. Data Transfer Commands.....	1733
15.5.6. Transfer Stop and Abort Commands.....	1739
15.5.7. Internal DMA Controller Operations.....	1741
15.5.8. Commands for SDIO Card Devices.....	1743
15.5.9. CE-ATA Data Transfer Commands.....	1746
15.5.10. Card Read Threshold.....	1753
15.5.11. Interrupt and Error Handling.....	1756
15.5.12. Booting Operation for eMMC and MMC.....	1757
15.6. SD/MMC Controller Address Map and Register Definitions.....	1768
15.6.1. sdmmc Address Map.....	1769
15.6.2. sdmmc_ecc Address Map.....	1841
16. Quad SPI Flash Controller.....	1874
16.1. Features of the Quad SPI Flash Controller.....	1874
16.2. Quad SPI Flash Controller Block Diagram and System Integration.....	1875
16.3. Quad SPI Flash Controller Signal Description.....	1876
16.4. Functional Description of the Quad SPI Flash Controller.....	1877
16.4.1. Overview.....	1877
16.4.2. Data Slave Interface.....	1877
16.4.3. SPI Legacy Mode.....	1881

16.4.4. Register Slave Interface.....	1882
16.4.5. Local Memory Buffer.....	1883
16.4.6. DMA Peripheral Request Controller.....	1883
16.4.7. Arbitration between Direct/Indirect Access Controller and STIG.....	1885
16.4.8. Configuring the Flash Device.....	1885
16.4.9. XIP Mode.....	1886
16.4.10. Write Protection.....	1887
16.4.11. Data Slave Sequential Access Detection.....	1887
16.4.12. Clocks.....	1887
16.4.13. Resets.....	1888
16.4.14. Interrupts.....	1888
16.5. Quad SPI Flash Controller Programming Model.....	1889
16.5.1. Setting Up the Quad SPI Flash Controller.....	1889
16.5.2. Indirect Read Operation with DMA Disabled.....	1890
16.5.3. Indirect Read Operation with DMA Enabled.....	1891
16.5.4. Indirect Write Operation with DMA Disabled.....	1891
16.5.5. Indirect Write Operation with DMA Enabled.....	1892
16.5.6. XIP Mode Operations.....	1892
16.6. Quad SPI Flash Controller Address Map and Register Definitions.....	1894
16.6.1. qspi_QSPIDATA Address Map.....	1895
16.6.2. qspi_regs Address Map.....	1895
16.6.3. qspi_ecc Address Map.....	1939
17. DMA Controller.....	1969
17.1. Features of the DMA Controller.....	1969
17.2. DMA Controller Block Diagram and System Integration.....	1971
17.3. Functional Description of the DMA Controller.....	1972
17.3.1. AXI Characteristics for a DMA Transfer.....	1973
17.3.2. Operating States.....	1974
17.3.3. Initializing the DMAC.....	1977
17.3.4. Using the Slave Interfaces.....	1979
17.3.5. Peripheral Request Interface.....	1980
17.3.6. Using Events and Interrupts.....	1990
17.3.7. Aborts.....	1992
17.3.8. Security Usage.....	1996
17.3.9. Programming Restrictions.....	2000
17.3.10. Constraints and Limitations of Use.....	2004
17.4. DMA Controller Programming Model.....	2005
17.4.1. Instruction Syntax Conventions.....	2005
17.4.2. Instruction Set Summary.....	2005
17.4.3. Instructions.....	2006
17.4.4. Assembler Directives.....	2023
17.4.5. MFIFO Buffer Usage Overview.....	2025
17.5. DMA Controller Address Map and Register Definitions.....	2032
17.5.1. DMA Controller Address Map and Register Definitions.....	2034
18. Ethernet Media Access Controller.....	2066
18.1. Features of the Ethernet MAC.....	2067
18.1.1. MAC.....	2067

21.5.1. Slave Mode Operation.....	4107
21.5.2. Master Mode Operation.....	4111
21.5.3. Disabling the I ² C Controller.....	4113
21.5.4. Abort Transfer.....	4114
21.5.5. DMA Controller Operation.....	4114
21.6. I ² C Controller Address Map and Register Definitions.....	4118
21.6.1. i2c Address Map.....	4118
21.6.2. i2c_emac Address Map.....	4185
22. UART Controller.....	4267
22.1. UART Controller Features.....	4267
22.2. UART Controller Block Diagram and System Integration.....	4268
22.3. UART Controller Signal Description.....	4269
22.3.1. HPS I/O Pins.....	4269
22.3.2. FPGA Routing.....	4269
22.4. Functional Description of the UART Controller.....	4270
22.4.1. FIFO Buffer Support.....	4270
22.4.2. UART(RS232) Serial Protocol.....	4270
22.4.3. Automatic Flow Control.....	4271
22.4.4. Clocks.....	4273
22.4.5. Resets.....	4273
22.4.6. Interrupts.....	4273
22.5. DMA Controller Operation.....	4276
22.5.1. Transmit FIFO Underflow.....	4277
22.5.2. Transmit Watermark Level.....	4277
22.5.3. Transmit FIFO Overflow.....	4279
22.5.4. Receive FIFO Overflow.....	4279
22.5.5. Receive Watermark Level.....	4279
22.5.6. Receive FIFO Underflow.....	4279
22.6. UART Controller Address Map and Register Definitions.....	4280
22.6.1. uart Address Map.....	4280
23. General-Purpose I/O Interface.....	4350
23.1. Features of the GPIO Interface.....	4350
23.2. GPIO Interface Block Diagram and System Integration.....	4351
23.3. Functional Description of the GPIO Interface.....	4351
23.3.1. Debounce Operation.....	4351
23.3.2. Pin Directions.....	4352
23.3.3. Taking the GPIO Interface Out of Reset	4352
23.4. GPIO Interface Programming Model.....	4352
23.5. General-Purpose I/O Interface Address Map and Register Definitions.....	4352
23.5.1. gpio Address Map.....	4353
24. Timer	4380
24.1. Features of the Timer.....	4380
24.2. Timer Block Diagram and System Integration.....	4380
24.3. Functional Description of the Timer.....	4381
24.3.1. Clocks.....	4382
24.3.2. Resets.....	4382
24.3.3. Interrupts.....	4382
24.4. Timer Programming Model.....	4383

24.4.1. Initialization.....	4383
24.4.2. Enabling the Timer.....	4383
24.4.3. Disabling the Timer.....	4383
24.4.4. Loading the Timer Countdown Value.....	4383
24.4.5. Servicing Interrupts.....	4384
24.5. Timer Address Map and Register Definitions.....	4384
24.5.1. timer_sys Address Map.....	4384
24.5.2. timer Address Map.....	4396
25. Watchdog Timer.....	4410
25.1. Features of the Watchdog Timer.....	4410
25.2. Watchdog Timer Block Diagram and System Integration.....	4411
25.3. Functional Description of the Watchdog Timer.....	4411
25.3.1. Watchdog Timer Counter.....	4411
25.3.2. Watchdog Timer Pause Mode.....	4412
25.3.3. Watchdog Timer Clocks.....	4412
25.3.4. Watchdog Timer Resets.....	4413
25.4. Watchdog Timer Programming Model.....	4413
25.4.1. Setting the Timeout Period Values.....	4413
25.4.2. Selecting the Output Response Mode.....	4413
25.4.3. Enabling and Initially Starting a Watchdog Timer.....	4414
25.4.4. Reloading a Watchdog Counter.....	4414
25.4.5. Pausing a Watchdog Timer.....	4414
25.4.6. Disabling and Stopping a Watchdog Timer.....	4414
25.4.7. Watchdog Timer State Machine.....	4414
25.5. Watchdog Timer Address Map and Register Definitions.....	4416
25.5.1. watchdog Address Map.....	4416
26. Hard Processor System I/O Pin Multiplexing.....	4434
26.1. Features of the HPS I/O Block.....	4434
26.2. HPS I/O Block Diagram and System Integration.....	4435
26.3. Functional Description of the HPS I/O.....	4437
26.3.1. Dedicated I/O Pins.....	4437
26.3.2. Shared I/O Pins.....	4438
26.3.3. FPGA Access.....	4439
26.3.4. Control Registers.....	4439
26.3.5. Configuring HPS I/O Multiplexing.....	4443
26.4. Test Considerations.....	4444
26.5. I/O Pin MUX Address Map and Register Definitions for Arria 10.....	4444
26.5.1. io48_pin_mux_shared_3v_io_grp Address Map.....	4444
26.5.2. io48_pin_mux_dedicated_io_grp Address Map.....	4504
26.5.3. io48_pin_mux_fpga_interface_grp Address Map.....	4556
27. Introduction to the HPS Component.....	4574
27.1. MPU Subsystem.....	4575
27.2. Arm CoreSight Debug Components.....	4575
27.3. Interconnect.....	4575
27.4. HPS-to-FPGA Interfaces.....	4575
27.5. Memory Controllers.....	4576
27.5.1. HPS SDRAM Controller.....	4576
27.6. Support Peripherals.....	4578
27.7. Interface Peripherals.....	4578

27.8. On-Chip Memories.....	4579

Bootling and Configuration	July 22, 2017

Table 2. Introduction to the Hard Processor System Revision History

Date	Version	Changes
May 2017	2017.05.31	Removed HMCREGS row from HPS Peripheral Region Map table. Accesses to this address block are not supported.
October 2016	2016.10.28	Renamed MPU Subsystem to Cortex-A9 MPCore*
May 2016	2016.05.27	Corrected the HPS-FPGA powering scheme.
May 2016	2016.05.03	Removed low-power double data rate 3 (LPDDR3) as a supported device.
November 2015	2015.11.02	Updated the link to the Memory Maps.
May 2015	2015.05.04	Corrected HPS-FPGA powering scheme.
December 2014	2014.12.15	Maintenance release
August 2014	2014.08.18	Initial release

Introduction to the Hard Processor System

Table 3. Clock Manager Revision History

Date	Version	Changes
July 2017	2017.07.22	<ul style="list-style-type: none">Replaced instances of EOSC1 pin with correct pin name, HPS_CLK1.Clarified that the osc1_clk signal is sourced from the HPS_CLK1 input pin.
October 2016	2016.10.28	<ul style="list-style-type: none">Added mpuc1k register (offset 0x0) to i_clk_mgr_alteragrp
May 2016	2016.05.27	<ul style="list-style-type: none">Removed references to f2h_emac*_ap_clk in the <i>Arria 10 Top Level Clocks</i> table. The Ethernet application interface (also called the switch interface) is not supported.Removed clk9cntr (offset 0x44) and clk15cntr (offset 0x5C) registers from the i_clk_mgr_mainpllgrpRemoved clk9cntr register (offset 0x44) from the i_clk_mgr_perpllgrpClarified the src fields of the clk*cntr registers in the i_clk_mgr_mainpllgrp and i_clk_mgr_perpllgrp <p>Removed references to PLL counter outputs C9-C15 from the following topics:</p> <ul style="list-style-type: none">Boot ClockPLLsFREF, FVCO, and FOUT Equations
May 2016	2016.05.03	Added a section titled "L4 Peripheral Clocks".
November 2015	2015.11.02	Updated Sections: <ul style="list-style-type: none">Clock Manager Block Diagram and System IntegrationPLL IntegrationSoftware Sequenced ClocksClock GatingBoot Clock

continued...

Date	Version	Changes
		Added Sections: <ul style="list-style-type: none"> Updating PLL Settings without a System Reset MPU Clock Scaling Updates: <ul style="list-style-type: none"> Removed references to PLL output C9 used as HMC PLL reference clock.
May 2015	2015.05.04	<ul style="list-style-type: none"> Updated Block Diagram with HMC block Added Arria 10 Top Level Clocks table Updated PLL Integration in Clock Manager figure Added Address Map and Register Descriptions
December 2014	2014.12.15	Clock Manager Block Diagram. Updated mux output route. NOC clock added. Peripheral Clocks block update C15 input for PLL1 has been removed throughout document.
August 2014	2014.08.18	Initial release.

[Clock Manager](#) on page 56

Table 4. Reset Manager Revision History

Date	Version	Changes
July 2017	2017.07.22	<ul style="list-style-type: none"> Removed references to EOSC1 and replaced them with the correct external oscillator pin name, HPS_CLK1. Clarified that the osc1_clk signal is sourced from the HPS_CLK1 pin.
October 2016	2016.10.28	Maintenance release.
May 2016	2016.05.03	Maintenance release.
November 2015	2015.11.02	Updated "Reset Pins" section.
May 2015	2015.05.04	"Slave Interface" and "Status Register" sections updated.
December 2014	2014.12.15	Maintenance release.
August 2014	2014.08.18	Initial release.

2. Introduction to the Hard Processor System

The Intel Arria 10 system-on-a-chip (SoC) is composed of two distinct portions- a dual-core Arm* Cortex-A9 hard processor system (HPS) and an FPGA. The HPS architecture integrates a wide set of peripherals that reduce board size and increase performance within a system. A dedicated security manager within the HPS supports secure boot with the ability to authenticate, decrypt and provide tamper event response.

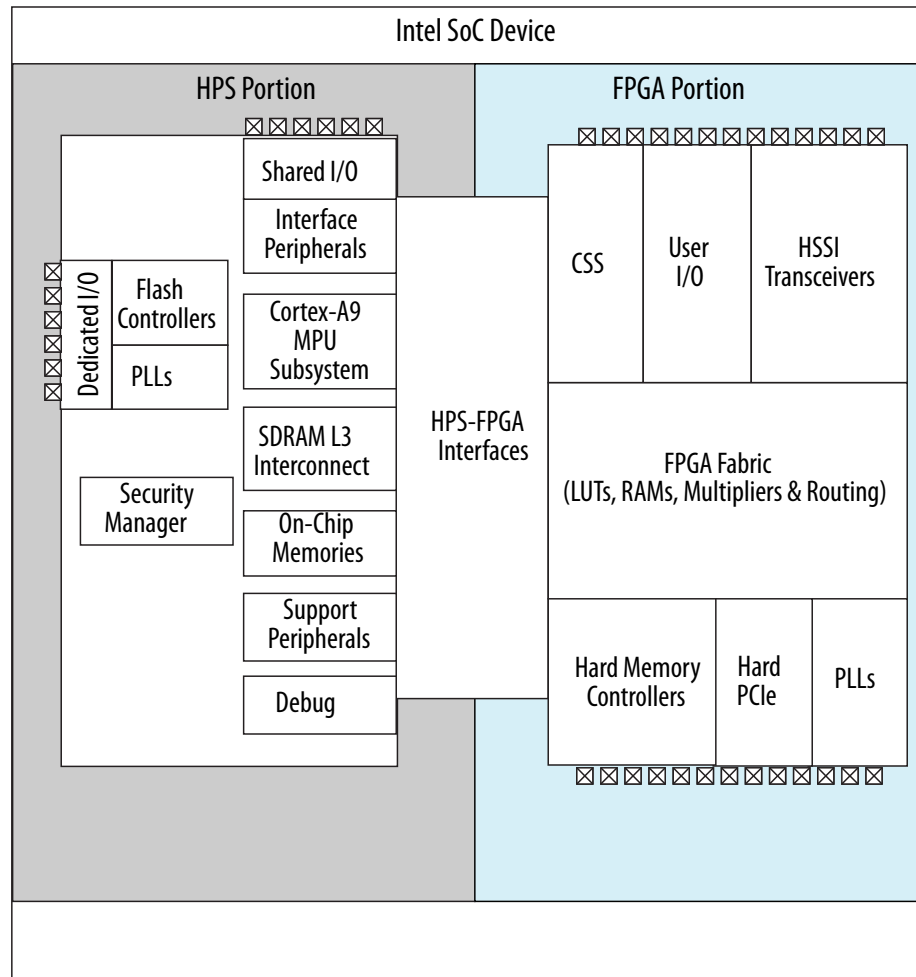

Figure 1 on page 33 shows a high-level block diagram of the Intel Arria 10 SoC device. Blocks connected to device pins have symbols (square with an X) adjacent to them in the figure.

The SoC features the following types of I/O pins:

- Dedicated I/O - I/O that is dedicated to an external non-volatile storage device (for boot ROM), HPS clock and resets.
- Shared I/O - I/O that can be assigned to peripherals in the HPS or FPGA logic.
- FPGA I/O - I/O that is dedicated to the FPGA fabric.

Figure 1. Intel SoC Device Block Diagram

The HPS consists of the following types of modules:

- Microprocessor unit (MPU) subsystem with a dual Arm Cortex-A9 MPCore processors
- Flash memory controllers
- SDRAM L3 interconnect
- System interconnect
- On-chip memories
- Support peripherals
- Interface peripherals
- Debug components
- Phase-locked loops (PLLs)

The HPS incorporates third-party intellectual property (IP) from several vendors.

The dual-processor HPS supports symmetric (SMP) and asymmetric (AMP) multiprocessing.

The FPGA portion of the device contains:

- FPGA fabric
- Configuration sub-system (CSS)
- PLLs
- High-speed serial interface (HSSI) transceivers, depending on the device variant
- Hard PCI Express* (PCI-e) controllers
- Hard memory controllers

The HPS and FPGA communicate with each other through bus interfaces that bridge the two distinct portions. On a power-on reset, the HPS can boot from multiple sources, including the FPGA fabric and external flash. The FPGA can be configured through the HPS or an externally supported device.

The HPS and FPGA portions of the device each have their own pins. The HPS has dedicated I/O pins and can also share some FPGA I/O pins. Pin assignments are configured when the HPS component is instantiated in Platform Designer. At boot time, software executing on the HPS assigns the I/O pins to the available HPS modules and configures the I/O pins through I/O control registers. For more information, refer to the "Hard Processor System I/O Pin Multiplexing" chapter. The FPGA I/O pins are configured by an FPGA configuration image through the HPS or any external source supported by the device.

The FPGA fabric and the HPS must be powered at the same time. Once powered, the FPGA fabric and the HPS can be configured independently thus providing you with more design flexibility:

- You can boot the HPS independently. After the HPS is running, the HPS can fully or partially reconfigure the FPGA fabric at any time under software control. The HPS can also configure other FPGAs on the board through the FPGA configuration controller.
- You can configure the FPGA fabric first, and then boot the HPS from the memory accessible to the FPGA fabric.

2.1. Features of the HPS

The main modules of the HPS are:

- MPU subsystem featuring a dual-core Arm Cortex-A9 MPCore processor
- System interconnect that includes three memory-mapped interfaces between the HPS and FPGA:
 - HPS-to-FPGA: 32-, 64-, or 128-bit wide AXI-4
 - Lightweight HPS-to-FPGA: 32-bit wide AXI-4
 - FPGA-to-HPS: 32-, 64-, or 128-bit wide ACE
- General-purpose direct memory access (DMA) controller
- Security manager
- Supports peripheral memories with single-error correction and double-error detection (SECDED)
- Three Ethernet media access controllers (EMACs)
- Two USB 2.0 on-the-go (OTG) controllers
- NAND flash controller
- Quad serial peripheral interface (QSPI) flash controller
- Secure digital/multimedia card (SD/MMC) controller
- Two serial peripheral interface (SPI) master controllers
- Two SPI slave controllers
- Five inter-integrated circuit (I²C) controllers⁽¹⁾
- 256 KB on-chip RAM
- 128 KB on-chip boot ROM
- Two UARTs
- Four system timers
- Two watchdog timers
- Three general-purpose I/O (GPIO) interfaces
- Arm CoreSight debug components:
 - Debug access port (DAP)
 - Trace port interface unit (TPIU)
 - System trace macrocell (STM)
 - Program trace macrocell (PTM)
 - Embedded trace router (ETR)
 - Embedded cross trigger (ECT)
- System manager

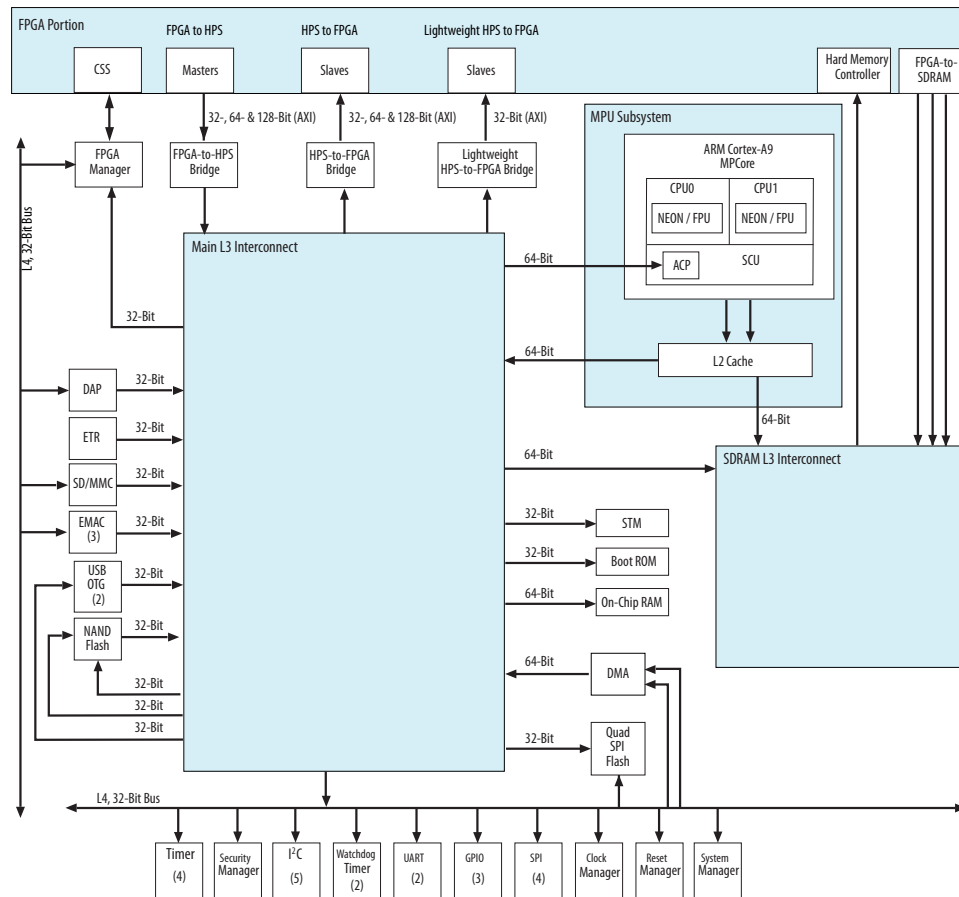

⁽¹⁾ Three of the five I²Cs, can optionally be configured to provide PHY management support for each EMAC controller.

- Clock manager
- Reset manager
- FPGA manager

2.2. HPS Block Diagram and System Integration

2.2.1. HPS Block Diagram

Figure 2. HPS Block Diagram

2.2.2. Cortex-A9 MPCore

The MPU subsystem is a stand-alone, full-featured Arm Cortex-A9 MPCore dual-core 32-bit application processor. It provides the following functionality:

- Arm Cortex-A9 MPCore
 - Two Arm Cortex-A9 processors
 - NEON* single instruction, multiple data (SIMD) coprocessor and vector floating-point v3 (VFPv3) per processor
 - Snoop control unit (SCU) to ensure coherency between processors
 - Accelerator coherency port (ACP) that accepts coherency memory access requests
 - Interrupt controller
 - One general-purpose timer and one watchdog timer per processor
 - Debug and trace features
 - 32 KB instruction and 32 KB data level 1 (L1) caches per processor
 - Memory management unit (MMU) per processor
- Arm L2-310 level 2 (L2) cache
 - Shared 512 KB L2 cache

As shown in the "HPS Block Diagram", the L2 cache has one 64-bit master port that is connected to the main L3 interconnect and one 64-bit master port connected to the SDRAM L3 interconnect. A programmable address filter in the L2 cache controls which portions of the 32-bit physical address space can be accessed by each master.

Related Information

[HPS Block Diagram](#) on page 36

2.2.3. HPS Interfaces

The Arria 10 device family provides multiple communication channels to the HPS.

2.2.3.1. HPS-FPGA Memory-Mapped Interfaces

The HPS-FPGA memory-mapped interfaces provide the major communication channels between the HPS and the FPGA fabric. The HPS-FPGA memory-mapped interfaces include:

- FPGA-to-HPS bridge—a high-performance bus with a configurable data width of 32, 64, or 128 bits, allowing the FPGA fabric to master transactions to the slaves in the HPS. This interface allows the FPGA fabric to have full visibility into the HPS address space. This interface also provides access to the coherent memory interface
- HPS-to-FPGA bridge—a high-performance interface with a configurable data width of 32, 64, or 128 bits, allowing the HPS to master transactions to slaves in the FPGA fabric
- Lightweight HPS-to-FPGA bridge—an interface with a 32-bit fixed data width, allowing the HPS to master transactions to slaves in the FPGA fabric

Related Information

[HPS-FPGA Bridges](#) on page 1007

2.2.3.2. Other HPS Interfaces

- TPIU trace—sends trace data created in the HPS to the FPGA fabric
- FPGA System Trace Macrocell (STM)—an interface that allows the FPGA fabric to send hardware events to be stored in the HPS trace data
- FPGA cross-trigger—an interface that allows the CoreSight trigger system to send triggers to IP cores in the FPGA, and vice versa
- DMA peripheral interface—multiple peripheral-request channels
- FPGA manager interface—signals that communicate with the FPGA fabric for boot and configuration
- Interrupts—allow soft IP cores to supply interrupts directly to the MPU interrupt controller
- MPU standby and events—signals that notify the FPGA fabric that the MPU is in standby mode and signals that wake up Cortex-A9 processors from a wait for event (WFE) state
- HPS debug interface – an interface that allows the HPS debug control domain (debug APB*) to extend into FPGA

Another HPS–FPGA communications channel is FPGA clocks and resets.

2.2.4. System Interconnect

The system interconnect consists of the main L3 interconnect, SDRAM L3 interconnect, and level 4 (L4) buses. The system interconnect is based on the Arteris*FlexNoC* network-on-chip (NoC) interconnect module. The system interconnect incorporates configurable secure firewalls protecting each peripheral.

The L4 buses are each connected to a master in the main L3 interconnect. Each L4 bus is 32 bits wide and is connected to multiple slaves. Each L4 bus operates on a separate clock source.

The SDRAM L3 interconnect consists of the SDRAM adapter and the SDRAM scheduler. SDRAM is protected by firewalls in the SDRAM L3 interconnect.

Related Information

- [System Interconnect](#) on page 364
- [Arria 10 HPS Secure Firewalls](#) on page 353

2.2.4.1. Arria 10 HPS SDRAM L3 Interconnect

The SDRAM L3 interconnect is part of the system interconnect and connects the HPS to the hard memory controller that is located in the FPGA fabric. The SDRAM L3 interconnect is composed of the SDRAM adapter and the SDRAM scheduler, which are secured by firewalls. It supports Arm Advanced Microcontroller Bus Architecture (AMBA*) Advanced eXtensible Interface (AXI) quality of service (QoS) for the fabric interfaces

The hard memory controller implements the following high-level features:

- Support for double data rate 3 (DDR3) and DDR4 devices
- Software-configurable priority scheduling on individual SDRAM bursts
- Error correction code (ECC) support, including calculation, single-bit error correction and write-back, and error counters
- Fully-programmable timing parameter support for all JEDEC-specified timing parameters
- All ports support memory protection and mutual-exclusive accesses
- FPGA-to-SDRAM interface—a configurable interface to the SDRAM scheduler in the SDRAM L3 interconnect You can configure the following parameters:
 - Up to three bridges
 - Up to 288 bits across all three ports

Related Information

[SDRAM L3 Interconnect Block Diagram and System Integration](#) on page 372

For more information on the components of the SDRAM L3 Interconnect and how they interface to the hard memory controller in the FPGA, refer to this diagram.

2.2.4.1.1. SDRAM Adapter

The SDRAM adapter is responsible for bridging the hard memory controller in the FPGA fabric to the SDRAM scheduler. The adapter is also responsible for error correction code (ECC) generation and checking.

2.2.4.1.2. SDRAM Scheduler

The SDRAM scheduler accepts read and write requests from the processor, HPS peripheral masters, and soft logic in FPGA through the FPGA-to-SDRAM interface. It is programmed with memory timings, allowing it to optimize memory access.

2.2.5. On-Chip Memory

2.2.5.1. On-Chip RAM

The on-chip RAM offers the following features:

- 256 KB size
- 64-bit slave interface
- High performance for all burst lengths
- ECC support provides detection of single-bit and double-bit errors and correction for single-bit errors
- Can clear the on-chip RAM on reset

Related Information

[On-Chip Memory](#) on page 1421

2.2.5.2. Boot ROM

The boot ROM offers the following features:

- 32-bit interface
- Capable of data transfers for every clock cycle
- 128 KB size
- Contains the code required to support both secure and non-secure HPS boot from cold or warm reset
- Used exclusively for booting the HPS

Related Information

- [On-Chip Memory](#) on page 1421
- [Booting and Configuration](#) on page 4634

2.2.6. Flash Memory Controllers

2.2.6.1. NAND Flash Controller

The NAND flash controller is based on the Cadence® Design IP® NAND Flash Memory Controller and offers the following functionality and features:

- Supports up to four chip selects. One chip select is connected to an HPS I/O pin and the rest can be connected to the FPGA I/O pins.
- Integrated descriptor-based DMA controller
- 8-bit and 16-bit ONFI 1.0 NAND flash devices
- Programmable page sizes of 512 bytes, 2 KB, 4 KB, and 8 KB
- Supports 32, 64, 128, 256, 384, and 512 pages per block
- Programmable hardware ECC for single-level cell (SLC) and multi-level cell (MLC) devices
- 512-byte ECC sector size with 4-, 8-, or 16-bit correction
- 1 KB ECC sector size with 24-bit correction

Related Information

[NAND Flash Controller](#) on page 1456

2.2.6.2. Quad SPI Flash Controller

The quad SPI flash controller is used for access to serial NOR flash devices. It supports standard SPI flash devices as well as high-performance dual and quad SPI flash devices. The Quad SPI flash controller is based on the Cadence Quad SPI Flash Controller and offers the following features:

- Supports SPIx1, SPIx2, or SPIx4 (Quad SPI) serial NOR flash devices
- Supports direct access and indirect access modes
- Supports single, dual, and quad I/O instructions
- Support up to four chip selects
- Programmable write-protected regions

- Programmable delays between transactions
- Programmable device sizes
- Support eXecute-In-Place (XIP) mode
- Programmable baud rate generator to generate device clocks

Related Information

[Quad SPI Flash Controller](#) on page 1874

2.2.6.3. SD/MMC Controller

The Secure Digital (SD), Multimedia Card (MMC), (SD/MMC) and CE-ATA host controller is based on the Synopsys DesignWare* Mobile Storage Host controller and offers the following features:

- Integrated descriptor-based DMA
- Supports CE-ATA digital protocol commands
- Supports single card
- Single data rate (SDR) mode only
- Programmable card width: 1-, 4-, and 8-bit
- Programmable card types: SD, SDIO, or MMC
- Up to 64 KB programmable block size
- Supports the following standards and card types:
 - SD, including eSD—version 3.0⁽²⁾
 - SDIO, including embedded SDIO (eSDIO)—version 3.0⁽³⁾
 - CE-ATA—version 1.1
- Supports various types of multimedia cards, MMC version 4.41⁽⁴⁾
 - MMC: 1-bit data bus
 - Reduced-size MMC (RSMMC): 1-bit and 4-bit data bus
 - MMCMobile: 1-bit data bus
- Supports embedded MMC (eMMC) version 4.5⁽⁵⁾
 - 1-bit, 4-bit, and 8-bit data bus

Note: For an inclusive list of the programmable card types and versions supported, refer to the *SD/MMC Controller* chapter.

Related Information

[SD/MMC Controller](#) on page 1685

⁽²⁾ Does not support SDR50, SDR104, and DDR50 modes.

⁽³⁾ Does not support SDR50, SDR104, and DDR50 modes.

⁽⁴⁾ Does not support DDR mode.

⁽⁵⁾ Does not support DDR and HS200 mode.

2.2.7. Support Peripherals

2.2.7.1. Clock Manager

The clock manager is responsible for providing software-programmable clock control to configure all clocks generated in the HPS. The clock manager offers the following features:

- Manages clocks for HPS
- Supports clock gating at the signal level
- Supports dynamic clock tuning

Related Information

[Clock Manager](#) on page 56

2.2.7.2. Reset Manager

The reset domains and sequences support several security features. The security manager brings the reset manager out of reset only when device security is confirmed. Afterwards, the reset manager brings the rest of the HPS system out of reset. The reset manager performs the following functions:

- Manages resets for HPS
- Controls the resets for cold, warm, debug, and TAP reset domains
- Controls the RAM clearing domain separately

Related Information

- [Reset Manager](#) on page 138
- [SoC Security](#) on page 332

2.2.7.3. Security Manager

The security manager module is integrated in the HPS and provides the overall management of security within the SoC, including:

- Recognition of secure fuse configuration, preventing non-secure device startup
- State control and check of the security features
- Secure boot options
- Secure debug options
- Anti-tamper support

Related Information

[SoC Security](#) on page 332

2.2.7.4. System Manager

The system manager contains logic to control system functions and logic to control other modules that need external control signals provided as part of system integration. The system manager offers the following features:

- Provides combined ECC status and interrupts from other HPS modules with ECC-protected RAM
- Low-level control of peripheral features not accessible through the control and status registers (CSRs)

Related Information

[System Manager](#) on page 244

2.2.7.5. System Timers

The HPS provides four 32-bit general-purpose timers connected to the level 4 (L4) peripheral bus. The four system timers are based on the Synopsys DesignWare Advanced Peripheral Bus (APB) Timers peripheral and offer the following features:

- 32-bit timer resolution
- Free-running timer mode
- Programmable time-out period up to approximately 86 seconds (assuming a 50 MHz input clock frequency)
- Interrupt generation

Related Information

[Timer](#) on page 4380

2.2.7.6. System Watchdog Timers

The two system watchdog timers are based on the Synopsys DesignWare APB Watchdog Timer peripheral and offer the following features:

- 32-bit timer resolution
- Interrupt request
- Reset request
- Programmable time-out period up to approximately 86 seconds (assuming a 50 MHz input clock frequency)

Note: Countdown can be paused when the MPU is in debug mode.

Related Information

[Watchdog Timer](#) on page 4410

2.2.7.7. DMA Controller

The DMA controller provides high-bandwidth data transfers for modules without integrated DMA controllers. The DMA controller is based on the Arm Corelink* DMA Controller (DMA-330) and offers the following features:

- Micro-coded to support flexible transfer types
 - Memory-to-memory
 - Memory-to-peripheral
 - Peripheral-to-memory
 - Scatter-gather
- Supports up to eight channels
- Supports flow control with 32 peripheral handshake interfaces

Related Information

[DMA Controller](#) on page 1969

2.2.7.8. FPGA Manager

The FPGA manager manages and monitors the FPGA portion of the SoC device. The FPGA manager can configure the FPGA fabric from the HPS, monitor the state of the FPGA, and drive or sample signals to or from the FPGA fabric.

Related Information

[FPGA Manager](#) on page 202

2.2.7.9. Error Checking and Correction Controller

ECC controllers provide single- and double-bit error memory protection for integrated on-chip RAM and peripheral RAMs within the HPS.

The following peripherals have integrated ECC-protected memories:

- USB OTG 0 - 1
- SD/MMC Controller
- EMAC 0 - 2
- DMA controller
- NAND flash controller
- QSPI flash controller

Features of the ECC controller:

- Single-bit error detection and correction
- Double-bit error detection
- Interrupts generated on single- and double-bit errors

Related Information

[Error Checking and Correction Controller](#) on page 1086

2.2.8. Interface Peripherals

2.2.8.1. EMACs

The three EMACs are based on the Synopsys DesignWare 3504-0 Universal 10/100/1000 Ethernet MAC and offer the following features:

- Supports 10, 100, and 1000 Mbps standard
- PHY interfaces supported through the HPS I/O pins:
 - Reduced media independent interface (RMII) and Reduced gigabit media independent interface (RGMII) through the HPS I/O pins
- PHY interfaces supported using adapter logic to route signals to the FPGA I/O pins:
 - Media independent interface (MII), Gigabit media independent interface (GMII), RMII, RGMII, and Serial gigabit media independent interface (SGMII) (with external conversion logic) through the FPGA pins
- Integrated DMA controller
- Supports IEEE 1588-2002 and IEEE 1588-2008 standards for precision networked clock synchronization
- IEEE 802.3-az, version D2.0 of Energy Efficient Ethernet
- Supports IEEE 802.1Q Virtual local area network (VLAN) tag detection for reception frames
- PHY Management control through Management data input/output (MDIO) interface or I²C interface
- 4 KB TX FIFO and 16 KB RX FIFO RAM
- Supports a variety of address filtering modes

Related Information

[Ethernet Media Access Controller](#) on page 2066

2.2.8.2. USB Controllers

The HPS provides two USB 2.0 Hi-Speed On-the-Go (OTG) controllers from Synopsys DesignWare. The USB controller signals cannot be routed to the FPGA like those of other peripherals; instead they are routed to the dedicated I/O.

Each of the USB controllers offers the following features:

- Complies with the following specifications:
 - USB OTG Revision 1.3
 - USB OTG Revision 2.0
 - Embedded Host Supplement to the USB Revision 2.0 Specification
- Supports software-configurable modes of operation between OTG 1.3 and OTG 2.0
- Supports all USB 2.0 speeds:
 - High speed (HS, 480-Mbps)
 - Full speed (FS, 12-Mbps)
 - Low speed (LS, 1.5-Mbps)

Note: In host mode, all speeds are supported; however, in device mode, only high speed and full speed are supported.

- Local buffering with Error Correction Code (ECC) support

Note: The USB 2.0 OTG controller does not support the following interface standards:

- Enhanced Host Controller Interface (EHCI)
 - Open Host Controller Interface (OHCI)
 - Universal Host Controller Interface (UHCI)
- Supports USB 2.0 Transceiver Macrocell Interface Plus (UTMI+) Low Pin Interface (ULPI) PHYs (SDR mode only)
- Supports up to 16 bidirectional endpoints, including control endpoint 0

Note: Only seven periodic device IN endpoints are supported.
- Supports up to 16 host channels

Note: In host mode, when the number of device endpoints is greater than the number of host channels, software can reprogram the channels to support up to 127 devices, each having 32 endpoints (IN + OUT), for a maximum of 4,064 endpoints.
- Supports generic root hub
- Supports automatic ping capability

Related Information

- [USB 2.0 OTG Controller](#) on page 3031
- [Universal Serial Bus \(USB\) website](#)

Additional information is available in the On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification, which you can download from the USB Implementers Forum website.

2.2.8.3. I²C Controllers

The five I²C controllers are based on Synopsys DesignWare APB I²C controller which offer the following features:

- Three controllers optionally can be used as a control interface for Ethernet PHY communication

Note: When an I²C controller is used for Ethernet, it will take the place of the MDIO pins.

- Support both 100 Kbps and 400 Kbps modes
- Support both 7-bit and 10-bit addressing modes
- Support master and slave operating mode
- Direct access for host processor
- DMA controller may be used for large transfers

Related Information

[I2C Controller](#) on page 4093

2.2.8.4. UARTs

The HPS provides two UART controllers to provide asynchronous serial communications. The two UART modules are based on Synopsys DesignWare APB Universal Asynchronous Receiver/ Transmitter peripheral and offer the following features:

- 16550-compatible UART
- Support automatic flow control as specified in 16750 standard
- Programmable baud rate up to 6.25 MBaud (with 100MHz reference clock)
- Direct access for host processor
- DMA controller may be used for large transfers
- 128-byte transmit and receive FIFO buffers
- Separate thresholds for DMA request and handshake signals to maximize throughput

Related Information

[UART Controller](#) on page 4267

2.2.8.5. SPI Master Controllers

The two SPI master controllers are based on Synopsys DesignWare Synchronous Serial Interface (SSI) controller and has a maximum bit rate of 60Mbps. The following features are offered:

- Programmable data frame size from 4 bits to 16 bits
- Supports full- and half-duplex modes
- Supports two chip selects connected to HPS I/O
- Supports four chip selects connected to the FPGA fabric
- Direct access for host processor
- DMA controller may be used for large transfers
- Programmable master serial bit rate

- Support for τ_{xd} sample delay
- Transmit and receive FIFO buffers are 256 words deep
- Choice of Motorola® SPI, Texas Instruments® Synchronous Serial Protocol or National Semiconductor® Microwire protocol

Related Information

[SPI Controller](#) on page 3982

2.2.8.6. SPI Slave Controllers

The two SPI slave controllers are based on Synopsys DesignWare Synchronous Serial Interface (SSI) controller and has a maximum bit rate of 50 Mbps. The following features are offered:

- Programmable data frame size from 4 bits to 16 bits
- Supports full- and half-duplex modes
- Direct access for host processor
- DMA controller may be used for large transfers
- Transmit and receive FIFO buffers are 256 words deep

Related Information

[SPI Controller](#) on page 3982

2.2.8.7. GPIO Interfaces

The HPS provides three GPIO interfaces that are based on Synopsys DesignWare APB General Purpose Programming I/O peripheral and offer the following features:

- Supports digital de-bounce
- Configurable interrupt mode
- Supports up to 17 dedicated 1.8 V and 3.0 V HPS I/O pins used for clock, reset, and external flash devices
- Supports up to 48 shared 3.0 V I/O pins that can be used by either the HPS or the FPGA. These pins are useful for Ethernet, USB, and other communication functions

Related Information

[General-Purpose I/O Interface](#) on page 4350

2.2.9. CoreSight Debug and Trace

The CoreSight debug and trace system offers the following features:

- Real-time program flow instruction trace through a separate PTM for each processor
- Host debugger JTAG interface
- Connections for cross-trigger and STM-to-FPGA interfaces, which enable soft IP cores to generate of triggers and system trace messages
- Custom message injection through STM into trace stream for delivery to host debugger
- Capability to route trace data to any slave accessible to the ETR master, which is connected to the level 3 (L3) interconnect

Related Information

[CoreSight Debug and Trace](#) on page 1064

2.2.10. Hard Processor System I/O Pin Multiplexing

The SoC has a total of 48 flexible I/O pins that are used for hard processor system (HPS) operation, external flash memories, and external peripheral communication. All of the 48 HPS I/O pins can also act as loaner I/O from the FPGA fabric. A pin multiplexing mechanism allows the SoC to use the flexible I/O pins in a wide range of configurations.

2.3. Endian Support

The HPS is natively a little-endian system. All HPS slaves are little endian.

The processor masters are software configurable to interpret data as little endian, big endian, or byte-invariant (BE8). All other masters, including the USB 2.0 interface, are little endian. Registers in the MPU and L2 cache are little endian regardless of the endian mode of the CPUs.

Note: Intel strongly recommends that you only use little endian.

The FPGA-to-HPS, HPS-to-FPGA, FPGA-to-SDRAM, and lightweight HPS-to-FPGA interfaces are little endian.

If a processor is set to BE8 mode, software must convert endianness for accesses to peripherals and DMA linked lists in memory. The processor provides instructions to swap byte lanes for various sizes of data.

The Arm Cortex-A9 MPU supports a single instruction to change the endianness of the processor and provides the REV and REV16 instructions to swap the endianness of bytes or half-words respectively. The MMU page tables are software configurable to be organized as little-endian or BE8.

The Arm DMA controller is software configurable to perform byte lane swapping during a transfer.

2.4. Introduction to the Hard Processor System Address Map

The address map specifies the addresses of slaves, such as memory and peripherals, as viewed by the MPU and other masters. The HPS has multiple address spaces, defined in the following section.

Related Information

[MPU Address Space](#) on page 381

2.4.1. HPS Address Spaces

The following table shows the HPS address spaces and their sizes.

Table 32. HPS Address Spaces

Name	Description	Size
MPU	MPU subsystem	4 GB
L3	System interconnect	4 GB
SDRAM	SDRAM region	4 GB

Address spaces are divided into one or more nonoverlapping regions. For example, the MPU address space has the peripheral, FPGA slaves, SDRAM window, and boot regions.

The following figure shows the relationships between the HPS address spaces. The figure is not to scale.

Figure 3. HPS Address Space Relationships

The SDRAM window in the MPU address space can grow and shrink at the top and bottom (short, blue vertical arrows) at the expense of the FPGA slaves and boot regions. For specific details, refer to "MPU Address Space".

The following table shows the base address and size of each region that is common to the L3 and MPU address spaces.

**Table 33. Common Address Space Regions**

Region Name	Base Address	Size
FPGA slaves	0xC0000000	960 MB
Peripheral	0xFC000000	64 MB
Lightweight FPGA slaves	0xFF200000	2 MB

2.4.1.1. SDRAM Address Space

The SDRAM address space is up to 4 GB. The entire address space can be accessed through the FPGA-to-SDRAM interface from the FPGA fabric. The total amount of SDRAM addressable from the other address spaces can be configured at runtime.

There are cacheable and non-cacheable views into the SDRAM space. When a master of the L3 SDRAM interconnect performs a cacheable access to the SDRAM, the transaction is performed through the ACP port of the MPU subsystem. When a master of the SDRAM L3 interconnect performs a non-cacheable access to the SDRAM, the transaction is performed through the 64-bit L3 interconnect master of the SDRAM L3 interconnect.

Related Information

[System Interconnect](#) on page 364

For more information about how to configure SDRAM address space.

2.4.1.2. MPU Address Space

The MPU address space is 4 GB and applies to addresses generated inside the MPU.

The MPU address space contains the following regions:

- The SDRAM window region provides access to a large, configurable portion of the 4 GB SDRAM address space.

The address filtering start and end registers in the L2 cache controller define the SDRAM window boundaries. The boundaries are megabyte-aligned. Addresses within the boundaries route to the SDRAM master. Addresses outside the boundaries route to the system interconnect master.

Related Information

For more information regarding SDRAM address mapping, refer to the System Interconnect chapter.
- [Cortex-A9 Microprocessor Unit Subsystem](#) on page 1022
- [HPS Address Spaces](#) on page 50

2.4.1.3. FPGA Slaves Address Space

The FPGA Slaves address space is located in the FPGA core and accessed from the HPS through the HPS2FPGA AXI Bridge. The FPGA Slaves address space in the FPGA core is of unlimited size (soft logic in the FPGA performs address decoding). The L3 and MPU

regions provide a window of nearly 1GB (actually 1GB less 64MB) into the FPGA Slaves address space. The base address of the FPGA Slaves Window is mapped to address 0x0 in the FPGA Slaves address space.

The HPS is able to boot from offset 0x0 into the FPGA Slaves address space (BSELselection).

2.4.1.4. LWFPGA Slaves Address Space

The Lightweight (LW) FPGA Slaves address space is located in the FPGA core and accessed from the HPS through the LWHP2FPGA Bridge. The LWFPGA Slaves address space in the FPGA core is of unlimited size (soft logic in the FPGA performs address decoding). A portion of the Peripheral region provides a window of 2MB into the LWFPGA Slaves address space. The base address of the LWFPGA Slaves window is mapped to address 0x0 in the LWFPGA Slaves address space.

The HPS is not able to boot from the LWFPGA Slaves address space.

2.4.1.5. L3 Address Space

The L3 address space is 4 GB and applies to all L3 masters except the MPU. The L3 address space has more configuration options than the other address spaces.

Related Information

[System Interconnect](#) on page 364

For more information about configuring the L3 address space, refer to the System Interconnect chapter.

2.4.2. HPS Peripheral Region Address Map

Each peripheral slave interface has a dedicated address range in the peripheral region. The table below lists the base address and address range size for each slave.

Table 34. Peripheral Region Address Map

Slave Identifier	Description	Base Address	Size
STM	STM module	0xFC000000	48 MB

3. Clock Manager

The hard processor system (HPS) clock generation is centralized in the clock manager. The clock manager is responsible for providing software-programmable clock control to configure all clocks generated in the HPS. Clocks are organized in clock groups. A clock group is a set of clock signals that originate from the same clock source. A phase-locked loop (PLL) clock group is a clock group where the clock source is a common PLL voltage-controlled oscillator (VCO).

[Intel Arria 10 Hard Processor System Technical Reference Manual Revision History](#) on page 17

For details on the document revision history of this chapter

3.1. Features of the Clock Manager

The *Clock Manager* offers the following features:

- Generates and manages clocks in the HPS
- Contains the following clock groups:
 - Main—contains clocks for the Cortex-A9 microprocessor unit (MPU) subsystem, level 3 (L3) interconnect, level 4 (L4) peripheral bus, and debug
 - Peripheral—contains clocks for PLL-driven peripherals
- Contains two identical 16-output PLL blocks:
 - PLL 0
 - PLL 1
- Generates clock gate controls for enabling and disabling most clocks
- Initializes and sequences clocks
- Allows software to program clock characteristics, such as the following items discussed later in this chapter:
 - Input clock source for the two PLLs
 - Multiplier range, divider range, and 16 post-scale counters for each PLL
 - VCO enable for each PLL
 - Bypass modes for each PLL
 - Gate of individual clocks in all PLL clock groups
 - Clear loss of lock status for each PLL
 - Boot mode for hardware-managed clocks
 - General-purpose I/O (GPIO) debounce clock divide

- Allows software to observe the status of all writable registers
- Supports interrupting the MPU subsystem on PLL-lock and loss-of-lock
- Supports clock gating at the signal level

The clock manager is **not** responsible for the following functional behaviors:

- Selection or management of the clocks for the FPGA-to-HPS and HPS-to-FPGA interfaces. The FPGA logic designer is responsible for selecting and managing these clocks.
- Software must not program the clock manager with illegal values. If it does, the behavior of the clock manager is undefined and could stop the operation of the HPS. The only guaranteed means for recovery from an illegal clock setting is a cold reset.
- When re-programming clock settings, there are no automatic glitch-free clock transitions. Software must follow a specific sequence to ensure glitch-free clock transitions. Refer to *Hardware-Managed and Software-Managed Clocks* section of this chapter.

3.2. Clock Manager Block Diagram and System Integration

Figure 4. Clock Manager Block Diagram

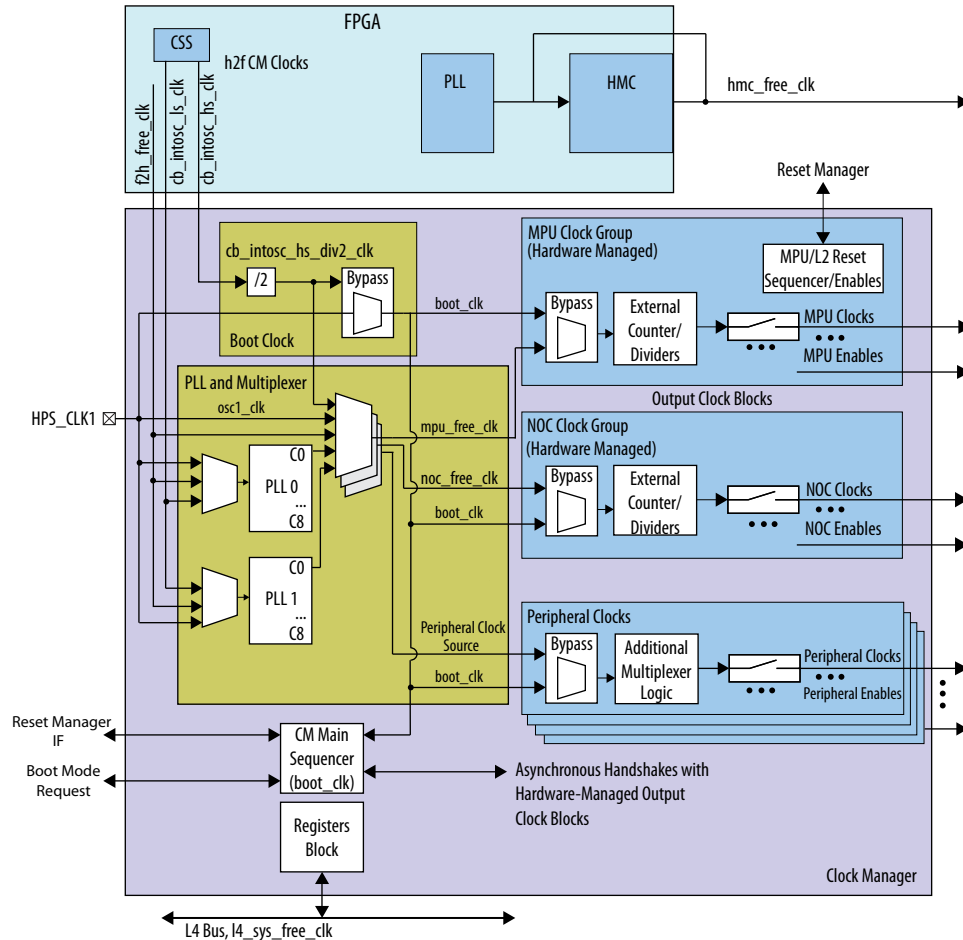

Table 35. Arria 10 Top Level Clocks

Clock Name	Source/Destination	Description
mpu_free_clk	Clock manager To MPU complex	Source clock from clock manager for both MPU clock groups.
mpu_clk	Internal to MPU complex	MPU main clock
mpu_l2ram_clk	Internal to MPU complex and HMC switch in NOC.	MPU L2 RAM clock and HMC switch in NOC. Fixed at 1/2 mpu_clk.
mpu_periph_clk	Internal to MPU complex	MPU peripherals clock for interrupts, timers, and watchdogs. Fixed at 1/4 mpu_clk.
l3_main_free_clk	Clock manager to NOC/Peripherals	Interconnect L3 main switch clock. Always free running.
l4_sys_free_clk	Clock manager to NOC/Peripherals	Interconnect L4 system clock. Always free running.

continued...

Clock Name	Source/Destination	Description
l4_main_clk	Clock manager to NOC/Peripherals	L4 Interconnect clock for fast peripherals including DMA, SPIM, SPIS and TCM.
l4_mp_clk	Clock manager to NOC/Peripherals	Interconnect L4 peripheral clock.
l4_sp_clk	Clock manager to NOC/Peripherals	Interconnect L4 slow peripheral clock.
cs_at_clk	Clock manager to CoreSight/NOC	CoreSight Trace clock and debug time stamp clock.
cs_pdbg_clk	Clock manager to CoreSight	CoreSight bus clock
cs_trace_clk	Clock manager to CoreSight	CoreSight Trace I/O clock. This will be independent and defaults to a low frequency (25 MHz) for lower speed debuggers. Not required to be sync. to other clocks (but keep in clock group as hardware managed)
cs_timer_clk	Clock manager to CoreSight/NOC	CoreSight timer clock. Same as cs_at_clk with different software enable to ensure MPU clock running. Not required to be sync. to other clocks (but still hardware managed).
fpga2soc_clk	FPGA fabric to NOC	FPGA to SoC interface clock from the FPGA.
soc2fpga_clk	FPGA fabric to NOC	SoC to FPGA interface clock from the FPGA.
lws2f_clk	FPGA fabric to NOC	LWHPS to FPGA interface clock from FPGA.
hmc_free_clk	From HMC to HMC switch in NOC	HMC interface clock from HMC (Hard Memory Controller) in FPGA.
f2h_sdram0_clk f2s_sdram1_clk f2h_sdram2_clk	FPGA fabric to HMC switch in NOC	FPGA fabric SDRAM write interfaces clocks.
f2h_pclkdbg	FPGA fabric to CoreSight bridge	CoreSight FPGA fabric APB debug port clock
usb[0,1]_ulpi_clk	I/O to USB	ULPI clock for PHY.

3.2.1. L4 Peripheral Clocks

The L4 peripheral clocks, denoted by l4_mp_clk, range up to 200 MHz.

Table 36. Clock List

Peripheral	Clock Name	Description
USB OTG 0/1 ⁽⁶⁾	hclk	AHB* clock
	pmu_hclk	PMU AHB clock. pmu_hclk is the scan clock for the PMU's AHB domain. <i>Note:</i> Select it as a test clock.
	utmi_clk	Always used as the PHY domain clock during DFT Scan mode.
<i>continued...</i>		

Peripheral	Clock Name	Description
		<i>Note:</i> Select <code>utmi_clk</code> as a test clock even when the core is configured for a non-UTMI PHY.
Quad SPI Flash Controller ⁽⁶⁾	<code>pclk</code>	APB clock
	<code>hclk</code>	AHB clock
NAND Flash Controller (Locally gated <code>nand_mp_clk</code>). ⁽⁶⁾	<code>ACLK</code>	AHB Data port clock
	<code>mACLK</code>	AXI Master port clock
	<code>regACLK</code>	AHB Register port clock
	<code>ecc_clk</code>	ECC circuitry clock
	<code>clk_x</code>	Bus Interface Clock
EMAC 0/1/2	<code>acclk</code>	Application clock for DMA AXI bus and CSR APB bus.
SD/MMC Controller	<code>sdmmc_clk</code>	All registers reside in the BIU clock domain.

For more information about the specific peripheral clocks, refer to their respective chapters.

3.2.2. Boot Clock

The Boot Clock (`boot_clk`) is used as the default clock for both cold or warm reset (Boot Mode), the Hardware Sequencer local clock and the external bypass clock reference.

The `boot_clk` is generated from the secure `cb_intosc_hs_div2_clk` or the unsecure external oscillator. `boot_clk` is only updated coming out of cold reset or a warm reset (boot mode request) and is not sampled at any other time.

The source of every output clock block comes from the following:

- Bypass source: `boot_clock` configured through fuses and security manager: registers at cold or warm reset
- Non-External Bypass: Each Clock may come from 1 of 5 sources:

⁽⁶⁾ Clock manager provides CSR bits for software enables to some peripherals. These enables are defaulted to enable. In boot mode, these enables are automatically active to ensure all clocks are active if RAM is cleared for security.

Table 37. Non-External Bypass Sources of clocks

Source	Description
OSC1	Pin for external oscillator
f2h_free_clk	FPGA fabric PLL clock reference
cb_intosc_hs_div2_clk	FPGA CSS (Control Block) high speed internal oscillator divided by 2 (200 MHz maximum)
PLL0 Counter Output	Main PLL counter outputs 0 to 8
PLL1 Counter Output	Peripheral PLL counter outputs 0 to 8

Clock Output Blocks have the following features:

- Each clock output block contains an external bypass multiplexer
- Some clock output blocks contain additional dividers
- Clock gates controlled by either hardware or software are used to disable the clocks
- The MPU and NOC (includes debug clocks) blocks contain enable outputs to define clock frequency ratios to the MPU, NOC and CoreSight logic

The CSR Register logic uses an independent clock, `l4_sys_free_clk`, to allow the clock to be changed by software.

3.2.2.1. Updating PLL Settings without a System Reset

Updating the PLL settings without a system reset will not reset the clock manager. All clocks will transition gracefully to their boot safe dividers. You can go in and out of boot mode and force the PLLs into bypass without doing a system reset. Software may reset the PLLs and reconfigure the VCO and bring it out of reset. By doing this you can safely update the PLL settings.

3.2.2.2. MPU Clock Scaling

You can dynamically slow down the MPU clock without touching the PLL by modifying the MPU external counter register (`MAINPLLGRP.MPUCLK.CNT`) to slow down the MPU frequency.

Related Information

[Clock Manager Address Map and Register Definitions](#) on page 71

3.3. Functional Description of the Clock Manager

3.3.1. Clock Manager Building Blocks

3.3.1.1. PLLs

The two PLLs in the clock manager generate the majority of clocks in the HPS. There is no phase control between the clocks generated by the two PLLs.

Each PLL has the following features:

- Phase detector and output lock signal generation
- Registers to set VCO frequency
 - Multiplier range is 1 to 4096
 - Divider range is 1 to 64
- 16 post-scale counters (C0-C8) with a range of 1 to 2048 to further subdivide the clock
- A PLL can be enabled to bypass all outputs to the input clock for glitch-free transitions

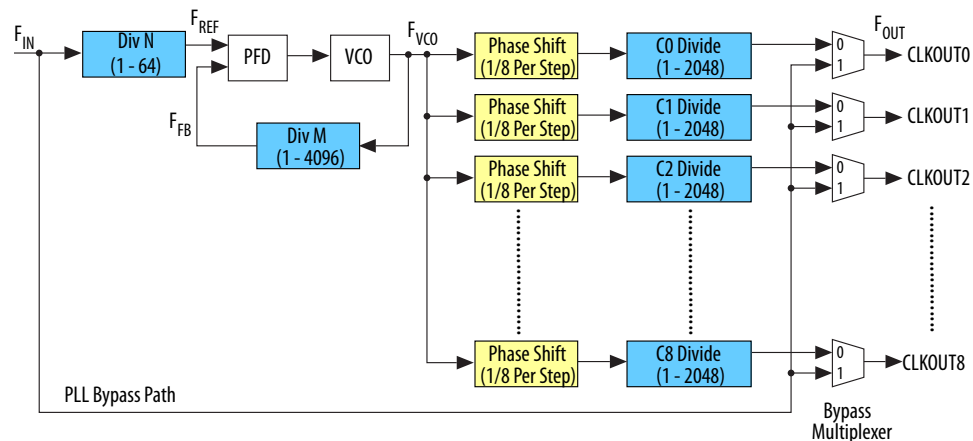

Related Information

- [PLL Integration](#) on page 63

- [Intel Intel Arria 10 Device Datasheet](#)

3.3.1.2. FREF, FVCO, and FOUT Equations

Figure 5. PLL Block Diagram

Values listed for M, N, and C are actually one greater than the values stored in the CSRs.

$$\begin{aligned}
 F_{REF} &= F_{IN} / N \\
 F_{VCO} &= F_{REF} \times M = F_{IN} \times M/N \\
 F_{OUT} &= F_{VCO} / C_1 = F_{REF} \times M/C_1 = (F_{IN} \times M) / (N \times C_1)
 \end{aligned}$$

where:

- FVCO = VCO frequency
- FIN = input frequency
- FREF = reference frequency
- FOUT = output frequency

- M = numerator, part of the clock feedback path
- N = denominator, part of the input clock reference path
- Ci = post-scale counter, where *i* is 0-8

The Ci dividers are used to derive lower frequencies from the PLLs. The M and N dividers can be dynamically updated without losing the PLL lock if the VCO frequency changes less than 20%. If changes greater than 20% are needed, iteratively changing the frequency in increments of less than 20% allows a slow ramp of the VCO frequency without loss of clock.

To minimize jitter, use the following guidelines:

- The VCO should be as close to maximum as possible
- It is better to use the Ci dividers than the N divider. The N divider should be kept as small as possible.
- The M divider should be minimized, but should be greater than 32.

When making any changes that affect the VCO frequency, software must put the PLL into external bypass. After changing the VCO frequency, software must wait for the PLL lock, as indicated by the `intrs` register or enabled interrupt, before taking the PLL out of bypass.

As shown in the "Hardware Clock Groups" and "Peripheral Clocks" figures, every clock has five possible sources. When switching between clock sources:

- Put PLL into bypass mode
- Change the mux select
- Switch back out of bypass mode

Note: The new clock source must be active and locked before exiting bypass mode.

As shown in the "PLL Integration in Clock Manager" figure, each PLL has multiple input sources. If the input source is changed, the PLL loses VCO lock and all output clocks are not reliable. Before switching the PLL input source, software must select the `boot_clk` bypass for all PLL0 and PLL1 clocks. After the PLL output clocks are bypassed, software can change the PLL source and reinitialize the PLL.

Unused clock outputs should be set to a safe frequency such as 50 MHz to reduce power consumption and improve system stability.

3.3.1.3. Clock Gating

Clock gating enables and disables clock signals. Refer to the Peripheral PLL Group Enable Register (`en`) for more information on what clocks can be gated.

Related Information

[Clock Manager Address Map and Register Definitions](#) on page 71

3.3.2. PLL Integration

The two PLLs contain exactly the same set of output clocks. PLL0 is intended to be used for the MPU and the NOC clocks. PLL1 is intended to be used as the 250 MHz Ethernet clock reference.

Figure 6. PLL Integration in Clock Manager

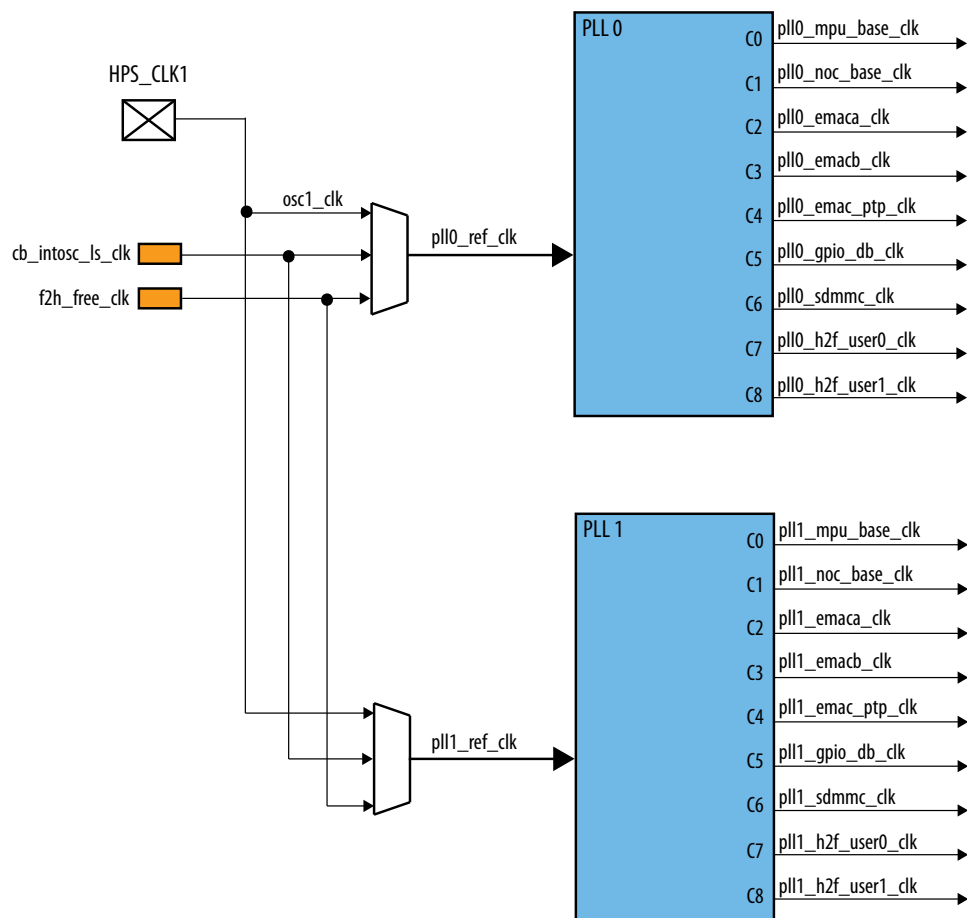

Table 38. PLL Output Clock Characteristics

Output Counter	Clock Name	Frequency	Boot Frequency
C0	mpu_base_clk	Up to varies	10 MHz to 200 MHz
C1	noc_base_clk	Up to C0/3	10 MHz to 200 MHz
C2	emaca_clk	50 to 250 MHz	10 MHz to 200 MHz
C3	emacb_clk	50 to 250 MHz	10 MHz to 200 MHz
C4	emac_ptp_clk	Up to 100 MHz	10 MHz to 200 MHz
C5	gpio_db_clk	Up to 200 MHz	10 MHz to 200 MHz
<i>continued...</i>			

(7) Frequency depends on device, refer to device datasheet for more information.

Output Counter	Clock Name	Frequency	Boot Frequency
C6	sdmmc_clk	Up to 200 MHz	10 MHz to 200 MHz
C7	h2f_user0_clk	Up to 400 MHz	10 MHz to 200 MHz
C8	h2f_user1_clk	Up to 400 MHz	10 MHz to 200 MHz

3.3.3. Hardware-Managed and Software-Managed Clocks

When changing values on clocks, the terms hardware-managed and software-managed define how clock transitions are implemented. When changing a software-managed clock, software is responsible for gating off the clock, waiting for a PLL lock if required, and gating the clock back on. Clocks that are hardware-managed are automatically transitioned by the hardware to ensure glitch-free operation.

- mpu_periph_clk
- mpu_l2_ram_clk
- mpu_clk
- l3_main_free_clk
- l4_sys_free_clk
- l4_sys_free_div4_clk
- l4_main_clk
- l4_mp_clk
- l4_sp_clk
- cs_timer_clk
- cs_at_clk
- cs_pdbg_clk
- cs_trace_clk

All other clocks in the HPS are software-managed clocks.

3.3.4. Hardware Sequenced Clock Groups

The hardware sequenced clock groups consists of the MPU clocks and the NOC clocks. The following diagram shows the external bypass muxes, hardware-managed external counters and dividers, and clock gates. For hardware-managed clocks, the group of clocks has only one software enable for the clock gate. As a result, the group of clocks are all enabled or disabled together. The slight exception is the NOC has two software enables, one for the I3/I4 clocks and one for the CoreSight clocks.

Figure 7. Hardware Clock Groups

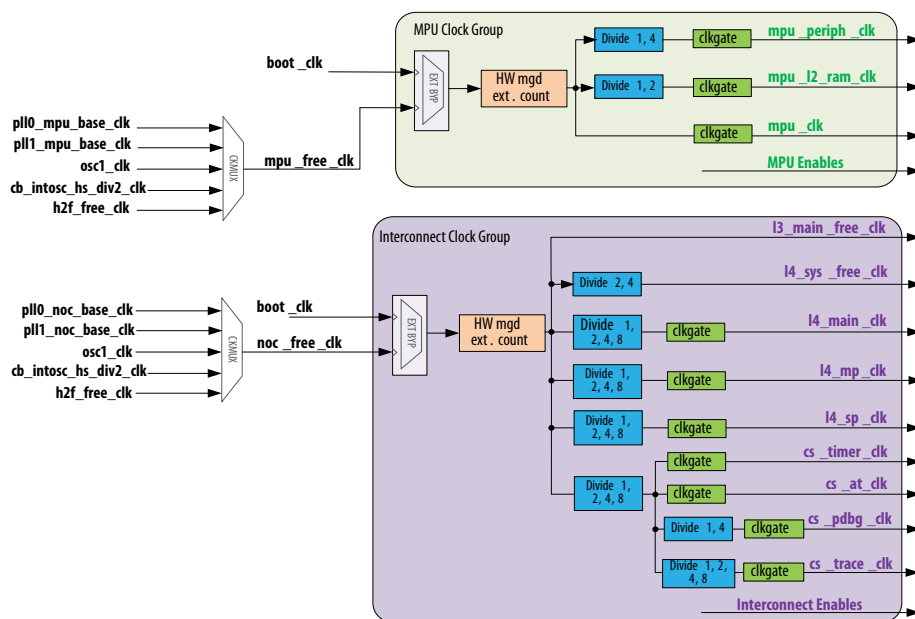

Table 39. The Hardware Sequenced Clocks Feature Summary

Clock Output Group	System Clock Name	Frequency	Boot Frequency	Uses
MPU	mpu_clk	PLL C0	boot_clk	MPU subsystem, including CPU0 and CPU1
	mpu_I2_ram_clk	mpu_clk/2	boot_clk	MPU level 2 (L2) RAM
	mpu_periph_clk	mpu_clk/4	boot_clk	MPU snoop control unit (SCU) peripherals, such as the general interrupt controller (GIC)
NOC	l3_main_free_clk	PLL C1	boot_clk	L3 interconnect
	l4_sys_free_clk	l3_main_free_clk/4	boot_clk/2	L4 interconnect
	l4_sys_free_div4_clk	l4_sys_free_clk/4	l4_sys_free_clk/4	L4 interconnect timer reference
	l4_main_clk	l3_main_free_clk/{1,2,4,8}	boot_clk	L4 main bus
continued...				

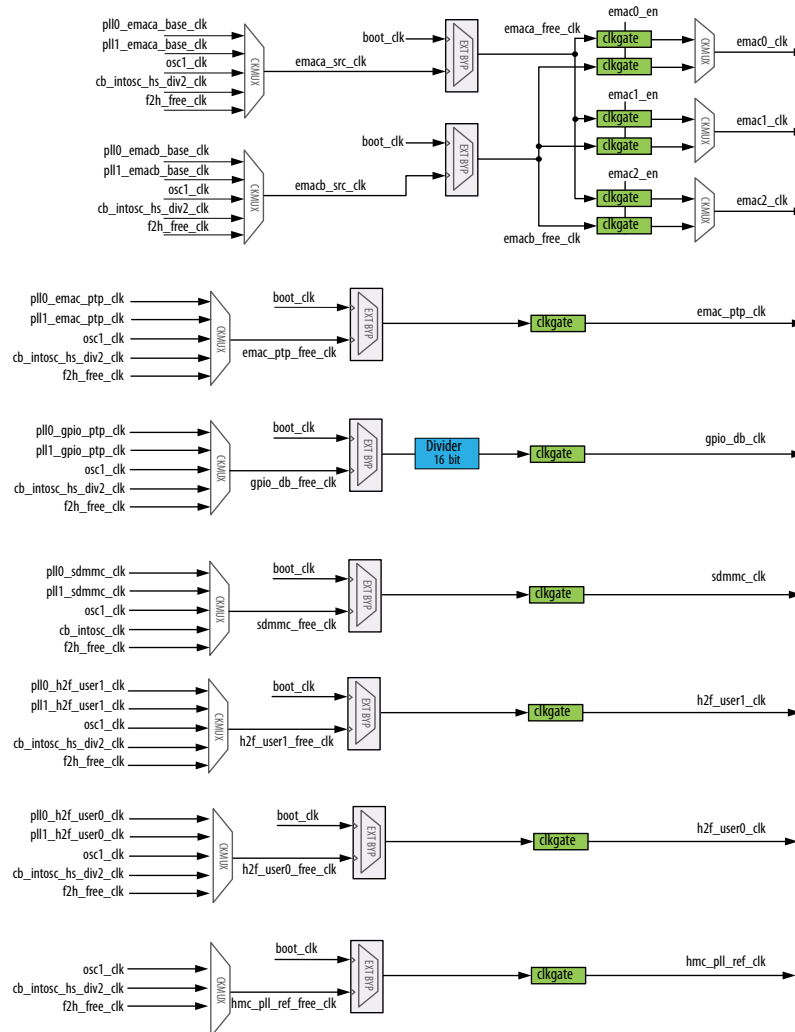

Clock Output Group	System Clock Name	Frequency	Boot Frequency	Uses
	l4_mp_clk	l3_main_free_clk/ {1,2,4,8}	boot_clk	L4 MP bus

	cs_trace_clk	cs_at_clk/{1,2,8}	cs_at_clk/4	Coresight debug Trace Port Interface Unit (TPIU)
Main FPGA Reference	h2f_user0_clk	h2f_user0_free_clk	boot_clk	FPGA
Main HMC PLL Reference	hmc_pll_ref_clk	hmc_pll_ref_free_clk	boot_clk	HMC FPGA IO PLL

3.3.5. Software Sequenced Clocks

The software sequenced clock groups include additional clocks for peripherals not covered by the NOC clocks. The main purpose is to have a second PLL for the Ethernet 250 MHz clock reference. The following diagram shows the external bypass muxes, hardware-managed external counters and dividers, and clock gates.

Figure 8. Peripheral Clocks

There are 3 EMAC cores that have a very strict requirement of either a 250 MHz or 50 MHz clock reference. If the PLL0 frequency is a multiple of 250 MHz (for example 1.5 GHz), driving the EMAC clocks from PLL0 provides PLL1 with more flexibility in VCO clock frequency. In addition, to minimize the PLL clock outputs required, `emac_clk_a` can be 250 MHz and `emac_clk_b` can be 50 MHz, allowing each EMAC core to be software configured to select 250 MHz or 50 MHz.

Table 40. Software Sequenced Clocks Feature Summary

System Clock Name	Frequency	Boot Frequency	Descriptions
emac{0,1,2}_clk	PLL C2 or PLL C3	boot_clk	Clock for EMAC. Fixed at 250 MHz or 250 MHz emac_clk and 50 MHz emacb_clk
emac_ptp_clk	PLL C4	boot_clk	Clock for EMAC PTP timestamp clock
gpio_db_clk	125 Hz to PLL C5	boot_clk	Clock for GPIO debounce clock
sdmmc_clk	PLL C6	boot_clk	Clock for SDMMC
h2f_user0_clk	PLL C7	boot_clk	Clock reference for FPGA
h2f_user1_clk	PLL C8	boot_clk	Clock reference for FPGA

3.3.6. Resets

Power-On-Reset (POR) Reset

The security manager handles clocking during POR. Depending on the status of one of the security fuses, the device is initially clocked using either the secure `cb_intosc_hs_div2_clk` or the unsecure external oscillator.

Cold Reset

The reset manager brings the clock manager out of cold reset first in order to provide clocks to the rest of the blocks. After POR is de-asserted, clock manager enables `boot_clk` to the rest of the system before the module resets are de-asserted.

Warm Reset

During a Warm Reset, the clock manager module is not reset. The following steps are taken during a warm reset:

1. Reset manager puts all modules affected by Warm Reset into reset. Reset manager issues a Boot Mode request to clock manager.
2. Based on the status of the `hps_clk_f` fuse during POR, security manager indicates if the boot clock should be secure.
 - a. If secure clocks are enabled, `boot_clk` transitions gracefully to `cb_intosc_hs_div2_clk`.
 - b. If secure clocks are not enabled, `boot_clk` transitions gracefully to the external oscillator input, `HPS_CLK1`.

Note: The security fuse is only sampled during cold reset and warm reset. The security fuse `hps_clk_f` allows the user to enable secure clocks. If clearing RAM on a Cold or Warm reset, the user should enable secure clocks (`cb_intosc_hs_clk` divide by 2).

3. The *Clock Manager* gracefully transitions Hardware-Managed and Software Managed clocks into Boot Mode as follows:
 - a. Disable all output clocks including Hardware and Software-Managed clocks.
 - b. Wait for all clocks to be disabled, and do the following two things:

- i. Bypass all external Hardware and Software-Managed clocks.
 - ii. Update Hardware-Managed external counters/dividers to Boot Mode settings.
- c. Wait for all bypasses to switch, and then synchronously reset the CSR registers.
- d. Enable all clocks.
4. After Hardware Managed Clocks have transitioned, the *Clock Manager* acknowledges the *Reset Manager*.
5. *Reset Manager* continues with Warm Reset de-assertion sequence.

3.3.7. Security

The clock manager creates a boot clock as the clock reference for boot mode and external bypass. The clock configuration is based on security features in the security manager.

Security Input Clocks

The following table defines the boot clock sources.

Table 41. Security Input Clocks

Clock Name	Max	Min	Source/Dest	Description
HPS_CLK1	50	10	Pin	External Oscillator Clock Reference. Non-secure clock reference. Named <i>osc1_clk</i> signal inside device.
cb_intosc_hs_clk	400	120	FPGA Control Block	Control Block high speed internal ring oscillator. This clock has wide variation across process/temperature. This clock is used as the secure reference for Boot Mode. Because the range/jitter of the clock is low quality, the clock is divided by 2.
cb_intosc_ls_clk	100	30	FPGA Control Block	Control Block low speed internal ring oscillator. This clock has wide variation across process/temperature. This clock is used by <i>Security Manager</i> as the Power on Reset Domain secure clock.
continued...				

Clock Name	Max	Min	Source/Dest	Description
				This clock is also provided as an input to the <i>Clock Manager</i> PLLs. However, because of the low quality of the clock, it is not recommended to use this clock as the PLL reference.

Boot Clock

The status of the `hps_clk_f` security fuse in the *Security Manager* determines if `boot_clk` should be secure:

- If set, then `boot_clk` is `cb_intosc_hs_clk` divided by 2.
- If clear, then `boot_clk` comes from the external oscillator input pin `HPS_CLK1`.

The above setting is reported by the security manager before the chip is brought out of cold reset. Also the security status may be updated by security option registers in the security manager.

3.3.8. Interrupts

The clock manager provides one interrupt output, which is enabled through the interrupt enable register (`intren`). The interrupt can be programmed to trigger twhen either the PLL achieves or loses its lock.

3.4. Clock Manager Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the [Arria 10 HPS Address Map and Register Definitions](#).

3.4.1. `clkmgr_clkmgrp` Address Map

Module Instance	Base Address	End Address
<code>i_clk_mgr_clkmgr</code>	0xFFD04000	0xFFD0403F

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

0	IDLE									
1	BUSY									

3.4.1.10. testioctrl

Contains fields setting the IO output select for Test Clock and Debug outputs. The dedicated IO outputs includes two outputs for the Main PLL clock outputs (PLL_CLK0 and PLL_CLK1), two outputs for the Peripheral PLL clock outputs (PLL_CLK2 and PLL_CLK3), and one output for miscellaneous debug for the Main and Peripheral PLL (PLL_CLK4).

The Test Clock and Debug outputs will only propagate to the dedicated IO based on the IO pinmux configuration. If Test Clocks are selected in the pinmux, then the selects in this register determine which PLL clocks and PLL debug signals will propagate to the IOs.

Module Instance	Base Address	Register Address
i_clk_mgr_clkmgr	0xFFD04000	0xFFD04020

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Internal signal within device is named osc1_clk.	1	cb_intosc_ls_clk (internal low speed oscillator)	2	f2h_free_clk (FPGA fabric PLL clock reference)	RW	0x0
Value	Description											
0	HPS_CLK1 (external oscillator input pin). Internal signal within device is named osc1_clk.											
1	cb_intosc_ls_clk (internal low speed oscillator)											
2	f2h_free_clk (FPGA fabric PLL clock reference)											
6	saten	Enables saturation behavior.	RW	0x1								
5	fasten	Enables fast locking circuit.	RW	0x0								
continued...												

Bit	Name	Description	Access	Reset
4	regextsel	If set to '1', the external regulator is selected for the PLL. If set to '0', the internal regulator is selected. It is strongly recommended to select the external regulator while the PLL is not enabled (in reset), and then disable the external regulator once the PLL becomes enabled. Software should simultaneously update the 'Enable' bit and the 'External Regulator Input Select' in the same write access to the VCO register. When the 'Enable' bit is clear, the 'External Regulator Input Select' should be set, and vice versa. The reset value of this bit is applied on a cold reset; warm reset has no effect on this bit.	RW	0x0
3	outrresetall	Before releasing Bypass, All Output Counter Reset must be set and cleared by software for correct clock operation. If '1', Reset phase multiplexer and all output counter state. So that after the assertion all the clocks output are start from rising edge align. If '0', phase multiplexer and output counter state not reset and no change to the phase of the clock outputs.	RW	0x0
2	en	If '1', VCO is enabled. If '0', VCO is in reset.	RW	0x0
1	pwrdsn	If '1', power down analog circuitry. If '0', analog circuitry not powered down.	RW	0x1
0	bgpwrdsn	If '1', powers down bandgap. If '0', bandgap is not power down.	RW	0x1

3.4.2.3. vco1

Contains settings that control the Main PLL VCO. The VCO1 register contains the numerator and denominator counter settings.

Module Instance	Base Address	Register Address
i_clk_mgr_mainpllgrp	0xFFD04040	0xFFD04044

Offset: 0x4

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved										denom RW 0x1					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				numer RW 0x1											

vco1 Fields

Bit	Name	Description	Access	Reset
21:1 6	denom	Denominator in VCO output frequency equation. For incremental frequency change, if the new value lead to less than 20% of the frequency change, this value can be changed without resetting the PLL. The Numerator and Denominator can not be changed at the same time for incremental frequency changed.	RW	0x1
12:0	numer	Numerator in VCO output frequency equation. For incremental frequency change, if the new value lead to less than 20% of the frequency change, this value can be changed without resetting the PLL. The Numerator and Denominator can not be changed at the same time for incremental frequency changed.	RW	0x1

3.4.2.4. en

Contains fields that control clock enables for Main Clocks.
1: The clock is enabled.
0: The clock is disabled.

Module Instance	Base Address	Register Address

outrst															
RW 0x0															

outrst Fields

Bit	Name	Description	Access	Reset
15:0	outrst	Resets the individual PLL output counter. For software to change the PLL output counter without producing glitches on the respective clock, SW must set the Output Counter Reset Register 'Output Counter Reset' bit. Software then polls the respective Output Counter Reset Acknowledge bit in the Output Counter Reset Ack Status Register. Software then writes the appropriate counter register, and then clears the respective Output Counter Reset bit. LSB 'outrst[0]' corresponds to PLL output clock C0, etc. If set to '1', reset output divider, no clock output from counter. If set to '0', counter is not reset. The reset value of this bit is applied on a cold reset; warm reset has no affect on this bit.	RW	0x0

3.4.2.20. outrststat

Contains Output Clock Counter Reset acknowledge status.

Module Instance	Base Address	Register Address
i_clk_mgr_mainpllgrp	0xFFD04040	0xFFD040A4

Offset: 0x64

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit	Name	Description	Access	Reset				
		<table><tr><th>Value</th><th>Description</th></tr><tr><td>3</td><td>MAIN</td></tr></table>	Value	Description	3	MAIN		
Value	Description							
3	MAIN							
6	saten	Enables saturation behavior.	RW	0x1				
5	fasten	Enables fast locking circuit.	RW	0x0				
4	regextsel	If set to '1', the external regulator is selected for the PLL. If set to '0', the internal regulator is slected. It is strongly recommended to select the external regulator while the PLL is not enabled (in reset), and then disable the external regulator once the PLL becomes enabled. Software should simulateously update the 'Enable' bit and the 'External Regulator Input Select' in the same write access to the VCO register. When the 'Enable' bit is clear, the 'External Regulator Input Select' should be set, and vice versa. The reset value of this bit is applied on a cold reset; warm reset has no affect on this bit.	RW	0x0				
3	ouresetall	Before releasing Bypass, All Output Counter Reset must be set and cleared by software for correct clock operation. If '1', Reset phase multiplexer and all output counter state. So that after the assertion all the clocks output are start from rising edge align. If '0', phase multiplexer and output counter state not reset and no change to the phase of the clock outputs.	RW	0x0				
2	en	If '1', VCO is enabled. If '0', VCO is in reset.	RW	0x0				
1	pwrdsn	If '1', power down analog circuitry. If '0', analog circuitry not powered down.	RW	0x1				
0	bgpwrdsn	If '1', powers down bandgap. If '0', bandgap is not power down.	RW	0x1				

3.4.3.3. vco1

Contains settings that control the Peripheral PLL VCO. The VCO1 register contains the numerator and denominator counter settings.

Module Instance	Base Address	Register Address
i_clk_mgr_perpllgrp	0xFFD040C0	0xFFD040C4

Offset: 0x4

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

outreset RW 0x0															

outrst Fields

Bit	Name	Description	Access	Reset
15:0	outreset	Resets the individual PLL output counter. For software to change the PLL output counter without producing glitches on the respective clock, SW must set the Output Counter Reset Register 'Output Counter Reset' bit. Software then polls the respective Output Counter Reset Acknowledge bit in the Output Counter Reset Ack Status Register. Software then writes the appropriate counter register, and then clears the respective Output Counter Reset bit. LSB 'outreset[0]' corresponds to PLL output clock C0, etc. If set to '1', reset output divider, no clock output from counter. If set to '0', counter is not reset. The reset value of this bit is applied on a cold reset; warm reset has no affect on this bit.	RW	0x0

3.4.3.18. outrststat

Contains Output Clock Counter Reset acknowledge status.

Module Instance	Base Address	Register Address
i_clk_mgr_perpllgrp	0xFFD040C0	0xFFD04124

Offset: 0x64

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

4. Reset Manager

The reset manager generates module reset signals based on reset requests from the various sources in the HPS and FPGA fabric, and software writing to the module-reset control registers. The reset manager ensures that a reset request from the FPGA fabric can occur only after the FPGA portion of the system-on-a-chip (SoC) device is configured.

The HPS contains multiple reset domains. Each reset domain can be reset independently. A reset may be initiated externally, internally or through software.

The Reset domains and sequences include security features. The security manager works with Power On Reset (POR) and brings the reset manager out of reset only when the secure fuses have been loaded and validated. Once this process is complete, the reset manager brings the rest of the HPS out of reset.

Table 42. HPS Reset Domains

Domain Name	Domain Logic	Module Master	Description
POR	Power on Reset. The entire HPS is reset.	Security Manager	After POR, the security manager comes out of reset and validates the security fuses. After validation, the reset manager is released from reset and proceeds to perform a cold reset on the HPS.
System Cold	Cold Reset. All of the HPS except security manager and POR fuse logic.	Reset Manager	Using the known security state, the HPS is placed in the default state, allowing software to boot. Cold reset is triggered by POR as well as other sources.
System Warm	System Warm (SW) is a warm reset. All of the HPS except security manager, POR, Fuse Logic, and test access port (TAP), and Debug domains are reset.	Reset Manager	Used to recover system from a non-responsive condition. Resets a subset of the HPS state reset by a cold reset. Only affects the system reset domain, which allows debugging (including trace) to operate through the warm reset. It is possible to mask a warm reset for some modules such that they are not affected.
<i>continued...</i>			

Domain Name	Domain Logic	Module Master	Description
Debug	All debug logic including most of the DAP, CoreSight™ components connected to the debug peripheral bus, trace, the microprocessor unit (MPU) subsystem, and the FPGA fabric.	Reset Manager	May be asserted by cold reset, the debugger or software. Used to recover debug logic from a non-responsive condition.
TAP	JTAG test access port (TAP) controller, which is used by the debug access port (DAP).	Reset Manager	Asserted by cold reset or by Software.
RAM Clear	The on-chip memories are cleared	Reset Manager	Memories may be cleared on cold or warm as indicated by the corresponding bits in the ramstat register.

The HPS supports the following reset types:

- System cold reset
 - Used to ensure the HPS is placed in a default state sufficient for software to boot
 - Triggered by a power-on reset and other sources
 - Resets all HPS logic that can be reset
 - Affects all reset domains
- System warm reset
 - Used to recover system from a non-responsive condition
 - Does not reset the Debug or TAP reset domain, allowing debug functions including trace to operate through out a warm reset
 - Masks allow software to exclude modules from warm reset. Exceptions for masks:
 - To maintain security, there is no mask for security manager
 - The MPU cannot be masked
 - RAM Clearing domain (if not masked) logic is reset
- Debug reset
 - Used to recover debug logic from a non-responsive condition
 - Only affects the debug reset domain
- TAP Reset
 - JTAG TAP controller is reset
 - Software may trigger TAP reset

4.1. Reset Manager Block Diagram and System Integration

The reset manager accepts reset requests from the security manager, FPGA control block, FPGA core, modules in the HPS, and reset pins and generates module reset signals. The reset manager receives security status from the security manager. The reset manager also has warm reset handshaking signals to support system reset behavior, clock manager interfaces, and the Anti-Tamper interface with security manager. The Boot clock (`boot_clk`) is used as the default clock for both cold or warm reset. When the device is configured to operate in secure mode, `boot_clk` is `cb_intosc_hs_div2_clk`. When the device is not in secure mode, `boot_clk` is sourced from the external oscillator input pin, `HPS_CLK1`.

The following figure shows a block diagram of the reset manager in the SoC device. For clarity, reset-related handshaking signals to other HPS modules and to the clock manager module are omitted.

Figure 9. Reset Manager Block Diagram

4.1.1. Reset Controller

In secure mode, all signals are synchronous to `boot_clk`. In non-secure mode, all signals are synchronous to the clock signal `osc1_clk` which is sourced from the external oscillator input pin, `HPS_CLK1`. The following table lists the reset sources external to the HPS.

Table 43. HPS External Reset Sources

Source	Description
<code>f2h_cold_rst_req_n</code>	Cold reset request from FPGA fabric (active low)
<code>f2h_warm_rst_req_n</code>	Warm reset request from FPGA fabric (active low)
<code>f2h_dbg_rst_req_n</code>	Debug reset request from FPGA fabric (active low)
<code>load_csr_filt</code>	Cold-only reset from FPGA control block (CB)
<code>nPOR</code>	Power-on reset pin (active low)
<code>nRST</code>	Warm reset pin (active low)

Table 44. HPS External Reset Outputs

Source	Description
<code>h2f_cold_rst_n</code>	Cold-only reset to FPGA fabric (active low)
<code>h2f_rst_n</code>	Cold or warm reset to FPGA fabric (active low)
<code>h2f_dbg_rst_n</code>	Debug reset (<code>dbg_rst_n</code>) to FPGA fabric (active low)

The reset controller performs the following functions:

- Accepts reset requests from the FPGA control block (CB), FPGA fabric, modules in the HPS, and reset pins
- Generates an individual reset signal for each module instance for all modules in the HPS
- Provides reset handshaking signals to support system reset behavior

The reset controller generates module reset signals from external reset requests and internal reset requests. External reset requests originate from sources external to the reset manager. Internal reset requests originate from control registers in the reset manager.

The reset controller supports the following cold reset requests:

- Security manager reset
- Cold reset request pin (`nPOR`)
- FPGA fabric
- FPGA CB
- Software cold reset request bit (`swcoldrstreq`) of the control register (`ctrl`)

The reset controller supports the following warm reset requests:

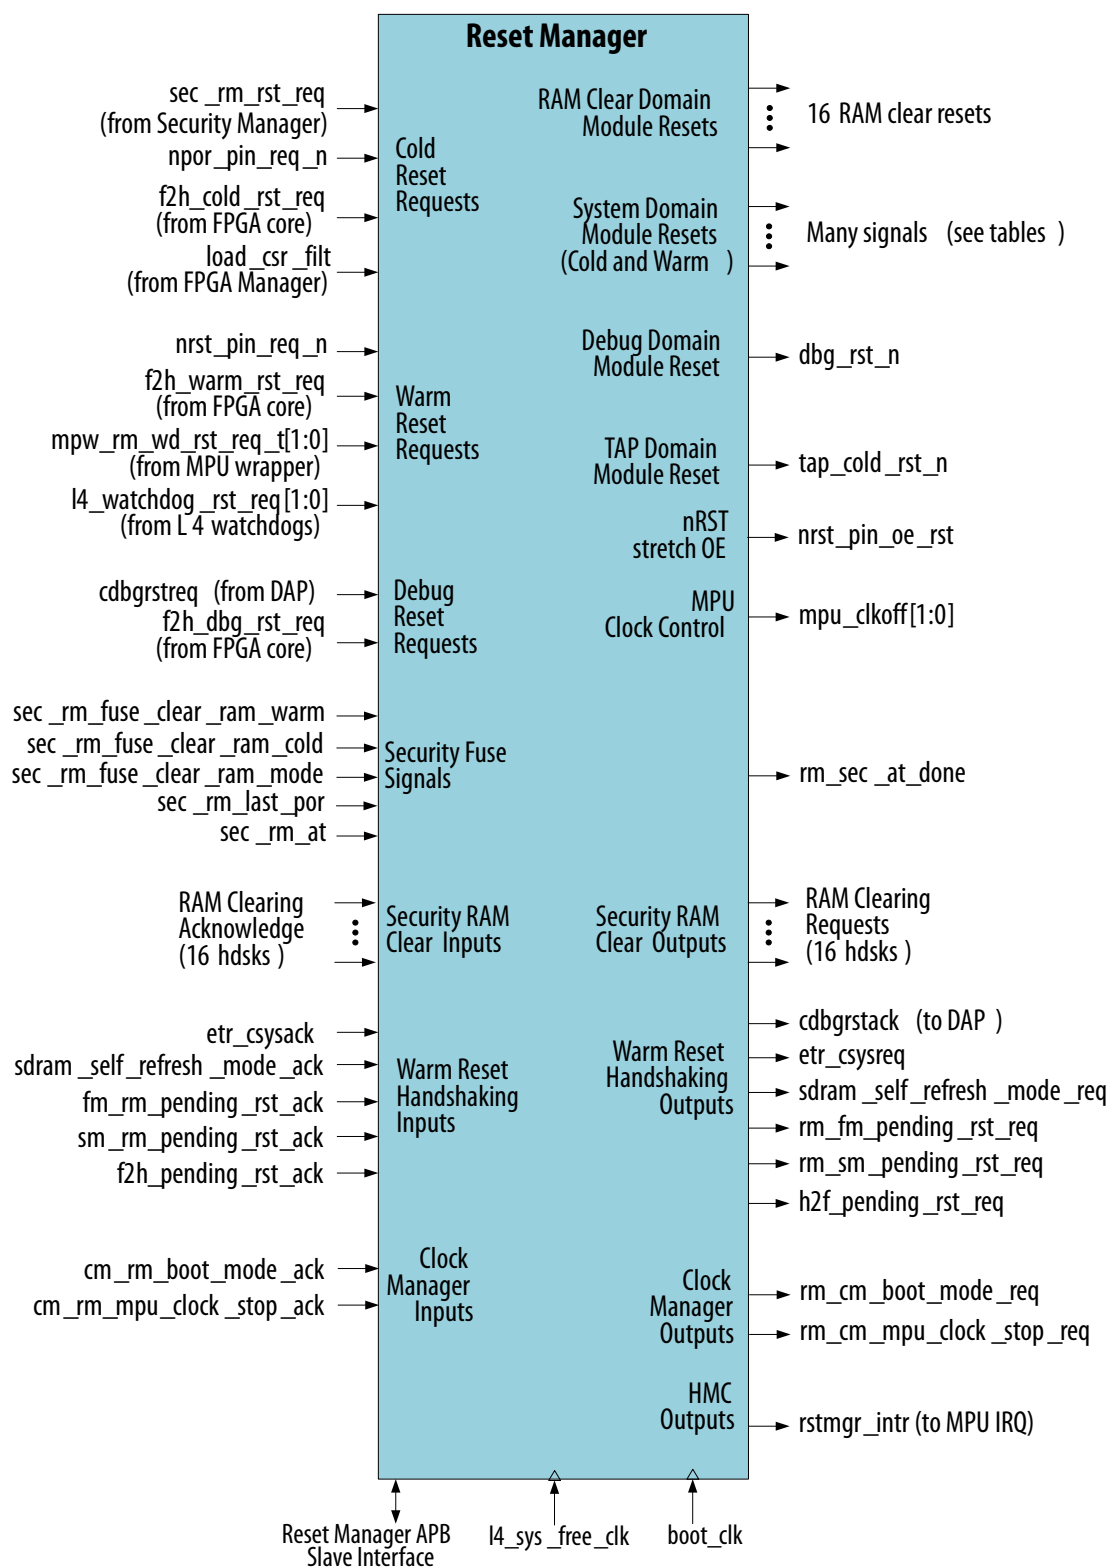

- Warm reset request pin (`nRST`)
- FPGA fabric
- Software warm reset request bit (`swwarmrstreq`) of the `ctrl` register
- MPU watchdog reset requests for CPU0 and CPU1
- System watchdog timer 0 and 1 reset requests

The reset controller supports the following debug reset requests:

- `CDBGIRSTREQ` from DAP
- FPGA fabric

Figure 10. Reset Controller Signals

4.1.2. Security Reset Functions

When secure mode is enabled on the device, reset manager performs some additional functions. To avoid unsecure snooping of existing RAM contents, the HPS can be configured to clear all RAM, both general-purpose RAM and dedicated RAM that is integrated into modules. The list of RAMs on the HPS is:

- Onchip RAM
- USB0
- USB1
- SDMMC
- EMAC0 - EMAC2 RX and TX buffers
- DMA
- NAND Read, Write and ECC RAMs
- QSPI
- MPU RAM

RAMs can be cleared on cold reset, warm reset or both as there are separate fuses that control behavior for cold and warm resets. When the corresponding fuse is blown, all RAMs are cleared for the indicated reset type. If an additional fuse is blown, the various RAM contents are cleared sequentially; otherwise, the contents of all of the RAMs are cleared simultaneously. Even if all security RAM clearing is disabled, the reset manager always invalidates the MPU L1 Cache.

The HPS also supports an Anti-Tamper interface from the FPGA fabric to security manager. If an Anti-Tamper event occurs, the HPS clears all RAMs and becomes unresponsive. The HPS only recovers from this state by a POR. Anti-Tamper logic, such as voltage detection, may reside in the FPGA.

4.1.3. Module Reset Signals

The following tables list the module reset signals. The module reset signals are organized in groups for the MPU, peripherals, bridges.

In the following tables, columns marked for Cold Reset, Warm Reset, and Debug Reset denote reset signals asserted by each type of reset. For example, writing a 1 to the `swwarmrstreq` bit in the `ctrl` register resets all the modules that have a checkmark in the Warm Reset column.

Note: For warm resets, software can set the `warmmask` registers to prevent the assertion of module reset signals to peripheral modules.

The column marked for Software Deassert denotes reset signals that are left asserted by the reset manager.

Table 45. MPU Group, Generated Module Resets

Module Reset Signal	Description	Reset Domain	Cold Reset	Warm Reset	Debug Reset	Software Deassert

4.1.3.1. Modules Requiring Software Deassert

The reset manager leaves the reset signal asserted on certain modules even after the rest of the HPS has come out of reset. These modules are likely to require software configuration before they can safely be taken out of reset.

When a module that has been held in reset is ready to start running, software can deassert the reset signal by writing to the appropriate register, shown in the following table.

Table 52. Module Reset Signals and Registers

HPS Peripheral	Reset Register	Module Reset Signal	Reset Group

4.1.4. Slave Interface and Status Register

The reset manager slave interface is used to control and monitor the reset states.

The status register (*stat*) in the reset manager contains the status of the reset requester. The register contains a bit for each monitored reset request. The *stat* register captures all reset requests that have occurred. Software is responsible for clearing the bits.

During the boot process, the Boot ROM copies the `stat` register value into memory before clearing it. After booting, you can read the value of the reset status register at memory address (`r0 + 0x0038`). For more information, refer to the "HPS State on Entry to the Second-Stage Boot Loader" section of the *Booting and Configuration* appendix.

4.2. Functional Description of the Reset Manager

The reset manager generates reset signals to modules in the HPS and to the FPGA fabric. The following actions generate reset signals:

- Software writing a 1 to the `swcoldrstreq` or `swwarmrstreq` bits in the `ctrl` register. Writing either bit causes the reset controller to perform a reset sequence.
- Software writing to the `mpumodrst`, `per0modrst`, `perlmodrst`, `brgmodrst`, `sysmodrst`, `coldmodrst`, `nrstmodrst` or `dbgmodrst` module reset control registers.
- Asserting reset request signals triggers the reset controller. All external reset requests cause the reset controller to perform a reset sequence.

Multiple reset requests can be driven to the reset manager at the same time. Cold reset requests take priority over warm and debug reset requests. Higher priority reset requests preempt lower priority reset requests. There is no priority difference among reset requests within the same domain.

If a cold reset request is issued while another cold reset is already underway, the reset manager extends the reset period for all the module reset outputs until all cold reset requests are removed. If a cold reset request is issued while the reset manager is removing other modules out of the reset state, the reset manager returns those modules back to the reset state.

If a warm reset request is issued while another warm reset is already underway, the first warm reset completes before the second warm reset begins. If the second warm reset request is removed before the first warm reset completes, the warm first reset is extended to meet the timing requirements of the second warm reset request.

The `nPOR` pin can be used to extend the cold reset beyond what the POR voltage monitor automatically provides. The use of the `nPOR` pin is optional and can be tied high when it is not required.

The `nRST` pin can be used to extend a warm reset. The `nRST` pin is tri-stated, and the Reset Manager stretches a warm reset by the count programmed in the CSR (`RSTMGR.COUNTS.NRSTCNT`) [doc however you usually do registers and bits] After the count has elapsed, 256 additional clocks cycles elapse before the `nRST` input is sampled again.

The reset manager contains the `stat` register that indicates which reset source caused a reset as well as the `ramstat` register that indicates which RAM modules were cleared during the last reset. After a cold reset is complete, all bits are cleared except for the bit(s) that indicate the source of the cold reset. If multiple cold reset requests

overlap with each other, the bit corresponding to the source that de-asserts its request last is set. If more than one source is de-asserted in the same cycle, the value of the bit corresponding to each source is set.

After a warm reset is complete, the bit(s) that indicate the source of the warm reset are set to 1. A warm reset doesn't clear any bits in the stat register, so bits corresponding to any reset source that has caused a warm reset since the last cold reset or since the bits were last cleared are set. Any bit can be manually cleared by writing a 1 to it.

If RAM memory is cleared during a Cold or Warm reset, then the `ramstat` register indicates which RAMs during the reset. Bits are cleared manually by writing a 1.

The hard memory controller (HMC) in the FPGA is reset by the reset manager using a GPIO. The HMC is reset only through software; resetting the HMC is not part of the operation of any reset sources.

4.2.1. Reset Sequencing

The reset controller sequences resets without software assistance. Module reset signals are asserted asynchronously and synchronously. The reset manager deasserts the module reset signals synchronous to the `boot_clk` clock. Module reset signals are deasserted in groups in a fixed sequence. All module reset signals in a group are deasserted at the same time.

The reset manager sends a request to the clock manager to put the clocks in boot mode, which creates a fixed and known relationship between the `boot_clk` clock and all other clocks generated by the clock manager.

After the reset manager releases the MPU subsystem from reset, CPU1 is left in reset and CPU0 begins executing code from the reset vector address. Software is responsible for deasserting CPU1 and other resets, as shown in MPU Group, Generated Module Resets Table. Software deasserts resets by writing the `mpumodrst`, `per0modrst`, `per1modrst`, `brgmodrst`, `sysmodrst`, `coldmodrst`, `nrstmodrst`, and `dbgmodrst` module-reset control registers.

Software can also bypass the reset controller and generate reset signals directly through the module-reset control registers. In this case, software is responsible for asserting module reset signals, driving them for the appropriate duration, and deasserting them in the correct order. The clock manager is not typically in boot mode during this time, so software is responsible for knowing the relationship between the clocks generated by the clock manager. Software must not assert a module reset signal that would prevent software from deasserting the module reset signal. For example, software should not assert the module reset to the processor executing the software.

Table 53. Minimum Pulse Width

Reset Type	Value
Warm Reset	200 ns
Cold Reset	6 <code>osc1_clk</code> cycles

Note: The `osc1_clk` clock signal is sourced from the external oscillator input, `HPS_CLK1`.

Figure 11. Cold Reset Timing Diagram

Figure 12. Warm Reset Timing Diagram

The cold and warm reset sequences consist of different reset assertion sequences and the same deassertion sequence. The following sections describe the sequences.

Note: Cold and warm reset affect only the `cpu0`, and by default `cpu1` is held in reset until the software running in the `cpu0` releases it.

4.2.1.1. Cold Reset Assertion Sequence

The following list describes the assertion steps for cold reset shown in the Cold Reset timing diagram:

1. Assert all module resets.
2. Wait for level cold reset requests to de-assert
3. Wait for 32 cycles, de-asserts clock manager cold reset
4. Wait the nRST count (default is 2048). De-assert NRST Output Enable.
5. Wait 256 clocks to allow the nRST pin to stabilize. Start sampling nRST input pin.
6. Wait for level warm reset requests to all de-assert.
7. Go to de-assertion sequence.

Related Information

[Cold and Warm Reset Deassertion Sequence](#) on page 154

4.2.1.2. Warm Reset Assertion Sequence

The following list describes the assertion steps for warm reset shown in the Warm Reset Timing Diagram:

1. Reset manager performs optional handshake configured by SW with debug ETR. Wait for acknowledge.
2. Reset manager performs optional handshake configured by SW handshake with FPGA core. Wait for acknowledge.
3. Reset manager performs optional handshakes configured by SW with SDRAM and FPGA manager. Wait for acknowledges.
4. Reset manager asserts module resets except for MPU watchdogs if the watchdogs were the source of the warm reset.
5. Wait for 8 cycles, then reset manger sends `rm_cm_boot_mode_req` to clock manager. Wait until the Clock Manager acknowledges.
6. Start nRST count if non-zero and a fixed counter to 128 (COUNTS.WARMRSCYCLES).
7. If nRST count non-zero, start 256 stretch counter after nRST count is done to allow the nRST pin to stabilize. After 256 clocks, sample input pin nRST.
8. Wait for level warm reset requests to de-assert, the nRST count to be zero and the fixed 128 count to be zero.
9. Go to de-assertion sequence.

Related Information

[Cold and Warm Reset Deassertion Sequence](#) on page 154

4.2.1.3. Cold and Warm Reset Deassertion Sequence

The following list describes the deassertion steps for both cold and warm reset shown in the Cold Reset Timing Diagram and Warm Reset Timing Diagram:

1. De-assert all RAM CLEAR resets. Reset Manager Initiates Clock Manager MPU clocks stop request.
2. Clock manager stops the MPU clocks and then waits 16 MPU clocks.
3. Clock manager asserts Clock stop acknowledge to Reset Manager.
4. Reset manager sees acknowledge and de-asserts L2 (`mpu_l2_rst_n`) reset only. Reset Manager de-asserts MPU stop request.
5. Clock manger sees request de-asserted. Wait 16 MPU clocks. Start MPU clocks, and Clock Manager de-asserts Clock stop acknowledge.
6. Reset manager sees de-assertion of acknowledge. Wait 16 cycles.
7. Reset manager asserts CPU0/1 CLKOFF signals and waits 32 cycles.
8. Reset manager de-asserts CPU0, CPU1, and SCU MPU resets (not WD). Wait 32 additional cycles.
9. De-assert CPU0/1 CLKOFF signals. Wait 16 cycles

10. Reset manager checks the Security fuse setting, and if the appropriate cold or warm reset fuse is set, do full RAM clearing sequence. Otherwise, clear only the MPU L1 RAM.
11. Wait for Security RAM Sequence to complete.
12. Assert again the CPU0, CPU1 and SCU MPU resets. Wait 16 cycles.
13. De-assert L3 reset, and if Cold Reset, de-assert DBG and COLD groups of resets. Wait for 100 cycles
14. De-assert SYS group module resets. Wait for 200 cycles.
15. Reset manager Initiates Clock Manager MPU clocks stop request.
16. Clock manager stops the MPU clocks and then waits 16 MPU clocks.
17. Clock manager asserts Clock stop acknowledge to Reset Manager.
18. Reset manager sees acknowledge and de-asserts L2 (mpu_l2_rst_n) reset only. Reset Manager de-asserts MPU stop request.
19. Clock manger sees request de-asserted. Wait 16 MPU clocks. Start MPU clocks, and Clock Manager de-asserts Clock stop acknowledge.
20. Reset manager sees de-assertion of acknowledge. Wait 16 cycles.
21. Reset manager asserts CPU0 CLKOFF signal(s) and waits 32 cycles.
22. Reset manager de-asserts remaining CPU0, SCU, and WD resets (no CPU1). Wait 32 additional cycles.
23. De-assert CPU0 CLKOFF signal(s). De-assertion sequence is finished.
24. Now SW should start running. SW to de-assert FPER/PER/SPER/BRIDGE/MPU2 resets.

4.2.2. Reset Pins

Figure 13. Reset Pins

The test reset (`nTRST`), test mode select (`TMS`), and test clock (`TCK`) pins are associated with the TAP reset domain and are used to reset the TAP controller in the DAP. These pins are not connected to the reset manager.

The `nPOR` and `nRST` pins are used to request cold and warm resets respectively. The `nRST` pin is an output as well. Any warm reset request causes the reset manager to drive the `rst_pin_oe_rst` output enable high, which drives the `nRST` pin low. The amount of time the reset manager pulls `nRST` low is controlled by the `nRST` pin count field (`nrstcnt`) of the reset cycles count register (`counts`); the default is 2048 clocks. This technique can be used to reset external devices (such as external memories) connected to the HPS.

4.2.3. Reset Effects

The following list describes how reset affects HPS logic:

- In the security manager domain, some status bits are cleared differently for cold and warm reset.
- The TAP reset domain ignores warm reset
- The Debug reset domain ignores warm reset
- The Clock Manager module is reset only by cold reset. After warm reset, the Clock Manager is put into Boot Mode.
- Each peripheral module and System Manager define reset behavior differently. See the appropriate control register for details.
- In the MPU module, the Watchdog Reset Status Registers are reset if an MPU Watchdog triggered the warm reset
- The Pin MUX is reset only by cold reset.

4.2.4. Reset Handshaking

The reset manager participates in several reset handshaking protocols to ensure other modules are safely reset.

Before issuing a warm reset, the reset manager performs a handshake with several modules to allow them to prepare for a warm reset. The handshake logic ensures the following conditions:

- Optionally the ETR master has no pending master transactions to the L3 interconnect
- Optionally preserve SDRAM contents during warm reset by issuing self-refresh mode request
- FPGA manager stops generating configuration clock
- Warns the FPGA fabric of the forthcoming warm reset

Similarly, the handshake logic associated with ETR also occurs during the debug reset to ensure that the ETR master has no pending master transactions to the L3 interconnect before the debug reset is issued. This action ensures that when ETR undergoes a debug reset, the reset has no adverse effects on the system domain portion of the ETR.

4.3. Reset Manager Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the [Arria 10 HPS Address Map and Register Definitions](#).

4.3.1. rst_mgr Address Map

Module Instance	Base Address	End Address

4.3.1.2. stat

The STAT register contains bits that indicate the reset source. For reset sources, a field is 1 if its associated reset requester caused the reset.

Software clears bits by writing them with a value of 1. Writes to bits with a value of 0 are ignored.

After a cold reset is complete, all bits are reset to their reset value except for the bit(s) that indicate the source of the cold reset. If multiple cold reset requests overlap with each other, the source de-asserts the request last will be logged. The other reset request source(s) de-assert the request in the same cycle will also be logged, the rest of the fields are reset to default value of 0.

After a warm reset is complete, the bit(s) that indicate the source of the warm reset are set to 1. A warm reset doesn't clear any of the bits in the STAT register; these bits must be cleared by software writing the STAT register.

Module Instance	Base Address	Register Address
i_rst_mgr_rstmgr	0xFFD05000	0xFFD05000

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

4.3.1.3. ramstat

The RAMSTAT register contains bits that indicate the security RAM clearing event during cold or warm reset for each RAM.

Software clears bits by writing them with a value of 1. Writes to bits with a value of 0 are ignored.

For MPU, there are separate bits for L1 invalidate only or full security clearing.

There is another bit for L1 invalidate timeout error only. The security RAM clearing does not have a timeout.

Module Instance	Base Address	Register Address
i_rst_mgr_rstmgr	0xFFD05000	0xFFD05004

Offset: 0x4

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

4.3.1.4. miscstat

The MISCSTAT register contains bits that indicate the timeout event. For timeout events, a field is 1 if its associated timeout occurred as part of a hardware sequenced warm/debug reset.

Software clears bits by writing them with a value of 1. Writes to bits with a value of 0 are ignored.

After a cold reset is complete, all bits are reset to their reset value except for the bit(s) that indicate the source of the cold reset. If multiple cold reset requests overlap with each other, the source de-asserts the request last will be logged. The other reset request source(s) de-assert the request in the same cycle will also be logged, the rest of the fields are reset to default value of 0.

After a warm reset is complete, the bit(s) that indicate the source of the warm reset are set to 1. A warm reset doesn't clear any of the bits in the MISCSTAT register; these bits must be cleared by software writing the STAT register.

Module Instance	Base Address	Register Address
i_rst_mgr_rstmgr	0xFFD05000	0xFFD05008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

ctrl Fields

Bit	Name	Description	Access	Reset
1	swwarmrstreq	This is a one-shot bit written by software to 1 to trigger a hardware sequenced warm reset. It always reads the value 0.	RW	0x0
0	swcoldrstreq	This is a one-shot bit written by software to 1 to trigger a cold reset. It always reads the value 0.	RW	0x0

4.3.1.6. hdsken

The CTRL register is used by software to control reset behavior. It includes fields for enable hardware handshake with other modules before warm reset.

Module Instance	Base Address	Register Address
i_rst_mgr_rstmgr	0xFFD05000	0xFFD05010

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												etrst allen RW 0x0	fpgah sen RW 0x0	fpgam grhse n RW 0x0	sdrse lfref en RW 0x0

hdsken Fields

Bit	Name	Description	Access	Reset
3	etrstallen	Software writes this field 1 to request to the ETR that it stalls its AXI master to the L3 Interconnect. Software waits for the ETRSTALLACK to be 1 and then writes this field to 0. Note that it is possible for the ETR to never assert ETRSTALLACK so software should timeout if ETRSTALLACK is never asserted.	RW	0x0
2	fpgahsen	This field controls whether to perform handshake with FPGA before asserting warm reset. If set to 1, the Reset Manager makes a request to the FPGA before asserting warm reset signals. However if FPGA is already in warm reset state, the handshake is not performed. If set to 0, the handshake is not performed	RW	0x0
1	fpgamgrhsen	Enables a handshake between the Reset Manager and FPGA Manager before a warm reset. The handshake is used to warn the FPGA Manager that a warm reset is coming so it can prepare for it. When the FPGA Manager receives a warm reset handshake, the FPGA Manager drives its output clock to a quiescent state to avoid glitches. If set to 1, the Manager makes a request to the FPGA Manager before asserting warm reset signals. However if the FPGA Manager is already in warm reset, the handshake is skipped. If set to 0, the handshake is skipped.	RW	0x0
0	sdrselfrefen	This field controls whether the contents of SDRAM devices survive a hardware sequenced warm reset. If set to 1, the Reset Manager makes a request to the SDRAM Controller Subsystem to put the SDRAM devices into self-refresh mode before asserting warm reset signals. However, if SDRAM is already in warm reset, Handshake with SDRAM is not performed.	RW	0x0

4.3.1.7. hdskreq

The CTRL register is used by software to control reset behavior. It includes fields for software to initiate the cold and warm reset, enable hardware handshake with other modules before warm reset, and perform software handshake. The software handshake sequence must match the hardware sequence. Software must de-assert the handshake request after asserting warm reset and before de-assert the warm reset.

Fields are only reset by a cold reset.

Module Instance	Base Address	Register Address
i_rst_mgr_rstmgr	0xFFD05000	0xFFD05014

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

hdscreq Fields

Bit	Name	Description	Access	Reset
3	etrstallreq	Software writes this field 1 to request to the ETR that it stalls its AXI master to the L3 Interconnect. Software waits for the ETRSTALLACK to be 1 and then writes this field to 0. Note that it is possible for the ETR to never assert ETRSTALLACK so software should timeout if ETRSTALLACK is never asserted.	RW	0x0
2	fpgahsreq	Software writes this field 1 to initiate handshake request to FPGA . Software waits for the FPGAHSAK to be active and then writes this field to 0. Note that it is possible for the FPGA to never assert FPGAHSAK so software should timeout in this case.	RW	0x0
1	fpgamgrhsreq	Software writes this field 1 to request to the FPGA Manager to idle its output clock. Software waits for the FPGAMGRHSACK to be 1 and then writes this field to 0. Note that it is possible for the FPGA Manager to never assert FPGAMGRHSACK so software should timeout in this case.	RW	0x0
0	sdrselfrefreq	Software writes this field 1 to request to the SDRAM Controller Subsystem that it puts the SDRAM devices into self-refresh mode. This is done to preserve SDRAM contents across a software warm reset. Software waits for the SDRSELFREFACK to be 1 and then writes this field to 0. Note that it is possible for the SDRAM Controller Subsystem to never assert SDRSELFREFACK so software should timeout if SDRSELFREFACK is never asserted.	RW	0x0

4.3.1.8. hdsckack

The CTRL register is used by software to control reset behavior. It includes fields for software to initiate the cold and warm reset, enable hardware handshake with other modules before warm reset, and perform software handshake. The software handshake sequence must match the hardware sequence. Software must de-assert the handshake request after asserting warm reset and before de-assert the warm reset.

Fields are only reset by a cold reset.

Module Instance	Base Address	Register Address
i_rst_mgr_rstmgr	0xFFD05000	0xFFD05018

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

counts Fields

Bit	Name	Description	Access	Reset
31:2 4	warmrstcycles	On a warm reset, the Reset Manager releases the reset to the Clock Manager, and then waits for the number of cycles specified in this register before releasing the rest of the hardware controlled resets.	RW	0x80
19:0	nrstcnt	The Reset Manager pulls down the nRST pin on a warm reset for the number of cycles specified in this register. A value of 0x0 is reserved. nRST assertion on a warm reset may be disabled by clearing NRSTWARMMASK.NRSTPINOE.	RW	0x80 0

4.3.1.10. mpumodrst

The MPUMODRST register is used by software to trigger module resets (individual module reset signals). Software explicitly asserts and de-asserts module reset signals by writing bits in the appropriate *MODRST register. It is up to software to ensure module reset signals are asserted for the appropriate length of time and are de-asserted in the correct order. It is also up to software to not assert a module reset signal that would prevent software from de-asserting the module reset signal. For example, software should not assert the module reset to the CPU executing the software.

Software writes a bit to 1 to assert the module reset signal and to 0 to de-assert the module reset signal.

All fields except CPU1 are only reset by a cold reset. The CPU1 field is reset by a cold reset. The CPU1 field is also reset by a warm reset if not masked by the corresponding MPUWARMMASK field.

Module Instance	Base Address	Register Address
i_rst_mgr_rstmgr	0xFFD05000	0xFFD05020

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

Reserved												scupe r RW 0x0	wds RW 0x0	cpu1 RW 0x1	cpu0 RW 0x0

mpumodrst Fields

Bit	Name	Description	Access	Reset
3	scuper	Resets SCU and peripherals. Peripherals consist of the interrupt controller, global timer, both per-CPU private timers, and both per-CPU watchdogs (except for the Watchdog Reset Status registers).	RW	0x0
2	wds	Resets both per-CPU Watchdog Reset Status registers in MPU.	RW	0x0
1	cpu1	Resets Cortex-A9 CPU1 in MPU. It is reset to 1 on a cold or warm reset. This holds CPU1 in reset until software is ready to release CPU1 from reset by writing 0 to this field. On single-core devices, writes to this field are ignored. On dual-core devices, writes to this field trigger the same sequence as writes to the CPU0 field (except the sequence is performed on CPU1).	RW	0x1
0	cpu0	Resets Cortex-A9 CPU0 in MPU. When software changes this field from 0 to 1, it triggers the following sequence: 1. CPU0 reset is asserted. cpu0 clkoff is de-asserted. 2. after 32 osc1_clk cycles, cpu0 clkoff is asserted. When software changes this field from 1 to 0, it triggers the following sequence: 1. CPU0 reset is de-asserted. 2. after 32 cycles, cpu0 clkoff is de-asserted. Software needs to wait for at least 64 osc1_clk cycles between each change of this field to keep the proper reset/clkoff sequence. Note that the osc1_clk signal is sourced from the external oscillator input pin, HPS_CLK1.	RW	0x0

4.3.1.11. per0modrst

The PEROMODRST register is used by software to trigger module resets for Peripheral Group and Fast Peripheral Group. Regular Peripheral Group resets are in the lower 2 bytes, and Fast Peripheral Group resets are in the upper 2 bytes. Software explicitly asserts and de-asserts module reset signals by writing bits in the appropriate *MODRST register. It is up to software to ensure module reset signals are asserted for the appropriate length of time and are de-asserted in the correct order. It is also up to software to not assert a module reset signal that would prevent software from de-asserting the module reset signal. For example, software should not assert the module reset to the CPU executing the software.

Software writes a bit to 1 to assert the module reset signal and to 0 to de-assert the module reset signal.

All fields are reset by a cold reset. All fields are also reset by a warm reset if not masked by the corresponding PERWARMMASK field.
The reset value of all fields is 1. This holds the corresponding module in reset until software is ready to release the module from reset by writing 0 to its field.

Module Instance	Base Address	Register Address

4.3.1.20. per1warmmask

The PER1WARMMASK register is used by software to mask the assertion of module reset signals for hardware sequenced warm resets. There is a writeable bit for each module reset signal that is asserted by default on a hardware sequenced warm reset. If the bit is 1, the module reset signal is asserted by a hardware sequenced warm reset. If the bit is 0, the module reset signal is not changed by a hardware sequenced warm reset. The bit assignments of the *WARMMASK registers match the corresponding *MODRST registers. Any module reset signals that are never asserted by a warm reset have reserved bit offsets and are tied to 0 (read as 0, writes are ignored).

All fields are only reset by a cold reset.

Module Instance	Base Address	Register Address
i_rst_mgr_rstmgr	0xFFD05000	0xFFD05048

Offset: 0x48

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

4.3.1.24. l3warmmask

The L3WARMMASK register is used by software to mask the assertion of module reset signals for hardware sequenced warm resets. There is a writeable bit for each module reset signal that is asserted by default on a hardware sequenced warm reset. If the bit is 1, the module reset signal is asserted by a hardware sequenced warm reset. If the bit is 0, the module reset signal is not changed by a hardware sequenced warm reset. The bit assignments of the *WARMMASK registers match the corresponding *MODRST registers. Any module reset signals that are never asserted by a warm reset have reserved bit offsets and are tied to 0 (read as 0, writes are ignored).

All fields are only reset by a cold reset.

Note that there is no module reset for the L3 interconnect in any *MODRST register because there would be no way for a master to remove the module reset to the L3 once asserted.

Module Instance	Base Address	Register Address
i_rst_mgr_rstmgr	0xFFD05000	0xFFD05058

5. FPGA Manager

The FPGA manager in the hard processor system (HPS) manages and monitors the FPGA portion of the system on a chip (SoC) device. The FPGA manager can configure the FPGA fabric from the HPS, monitor the state of the FPGA, and drive or sample signals to or from the FPGA fabric.

Related Information

[Intel Arria 10 Hard Processor System Technical Reference Manual Revision History](#) on page 17

For details on the document revision history of this chapter

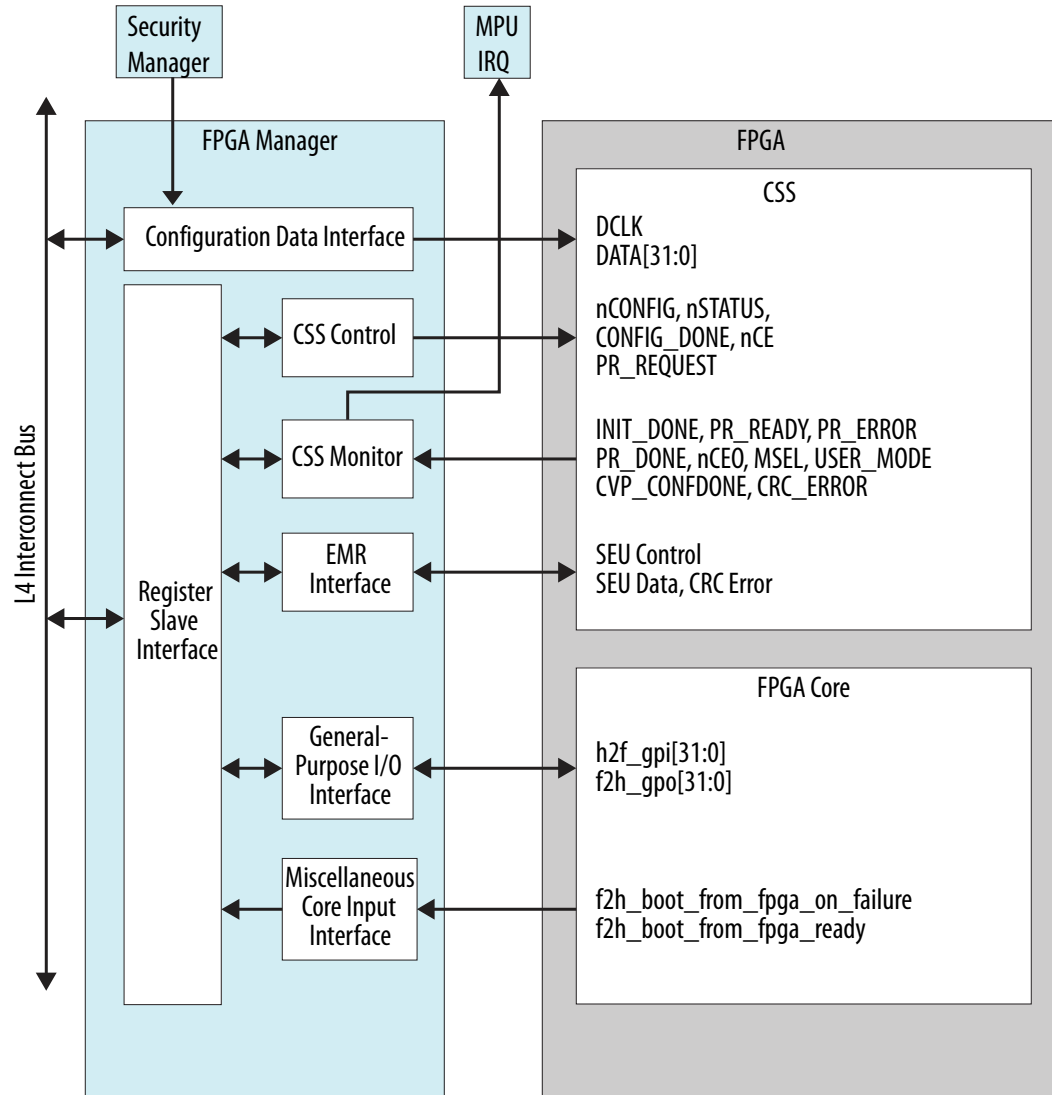

5.1. Features of the FPGA Manager

The FPGA manager provides the following functionality and features:

- Full configuration and partial reconfiguration
- CRC error message extraction
- General purpose I/O signals to the FPGA
- Boot from FPGA control
- Generation of interrupts based on FPGA status changes

5.2. FPGA Manager Block Diagram and System Integration

Figure 14. FPGA Manager Block Diagram

The FPGA Manager consists of the following blocks:

- Configuration Data Interface - Accepts and transfers the configuration and decryption data to the FPGA configuration sub system (CSS)
- Register Slave Interface - Accesses the control and status registers in the FPGA Manager
- CSS Control - Controls full and partial configuration of the FPGA
- CSS Monitor - Monitors the status of the FPGA during a full or partial configuration of the device

- Error Message Register (EMR) Interface - Error message extraction, in case of CRC errors in the FPGA
- General Purpose I/O Interface - Receives and drives 32 bits of general purpose I/O to and from the FPGA
- Miscellaneous Core Input Interface - Receives control input signals from the FPGA to support booting the HPS from the FPGA

5.3. Functional Description of the FPGA Manager

5.3.1. FPGA Configuration

You can configure the FPGA using an external device or through the HPS. This section highlights configuring the FPGA through the HPS.

The FPGA manager connects to the configuration logic in the FPGA portion of the device using a mode similar to how external logic (for example, MAX II or an intelligent host) configures the FPGA in fast passive parallel (FPP) mode. FPGA configuration through the HPS supports all the capabilities of FPP mode, including the following items:

- FPGA configuration
- Partial FPGA reconfiguration
- Decompression
- Advanced Encryption Standard (AES) encryption

Note: The FPGA manager supports a data width of 16 or 32 bits. When configuring the FPGA fabric from the HPS, Intel recommends that you always set the data width to 32 bits. For partial reconfiguration, the 16-bit and 32-bit data widths are options.

Table 54. MSEL Pin Settings for Each Configuration Scheme of Arria 10 Devices

Configuration Scheme	V _{CCPGM} (V)	Power-On Reset (POR) Delay	Valid MSEL[2:0]
FPP (x16 and x32)	1.8	Fast	000
		Standard	001

The FPGA Manager can be configured to accept configuration data directly from the MPU or the DMA engine. Either the processor or the DMA engine moves data from memory to the FPGA Manager data image register space `img_data_w`.

Configuration data is buffered in a 64 deep x 32 bits wide FIFO in the FPGA Manager. Status information such as FIFO empty/full and remaining depth can be accessed through a status register `imgcfg_stat`. FIFO empty/full conditions can also be enabled to generate an interrupt.

If using the DMA engine to move FPGA configuration data to the FPGA Manager, a FIFO threshold value can be set in the `dma_config` register. This value is used to control the assertion of a DMA transfer request from the FPGA Manager to the DMA engine.

Before sending FPGA configuration data to the FPGA Manager HPS, software sets the clock-to-data ratio field (CDRATIO) and configuration data width bit (CFGWIDTH) in the image control 2 register (imgcfg_ctrl_02).

- [Booting and Configuration](#) on page 4634

5.3.2. FPGA Status

Configuration signals from the FPGA CSS such as INIT_DONE, CRC_ERROR and PR_DONE are monitored by the FPGA Manager. Software configures the monitor block through the register slave interface, and can either poll FPGA signals or be interrupted. Monitored signals can be read through the imgcfg_stat register as well as the intr_masked_status register. Each of the monitored signals can generate an interrupt to the MPU global interrupt controller. Each interrupt source can be enabled and the polarity of the signals generating the interrupt can also be selected through the intr_mask and intr_polarity registers in the FPGA Manager.

5.3.3. Error Message Extraction

Cyclic redundancy check (CRC) errors from the FPGA fabric are monitored by the FPGA Manager. Upon assertion of a CRC error signal from the FPGA, the FPGA Manager extracts information about the error including:

- Error syndrome
- Error location
- Error type

A CRC error interrupt from the FPGA manager can be enabled through software. Software can then extract the CRC error information from the error message register (EMR) data interface. The number of valid error information bits in the EMR data registers depends on the specific FPGA device.

5.3.4. Data AES Decryption

The configuration data interface can also be used to transmit data from the HPS to the FPGA CSS Advanced Encryption Standard (AES) decryption engine. Software should sample the status registers in FPGA manager before switching modes between FPGA configuration and AES decryption. The FPGA manager does not do anything specific to handle a situation where software starts an AES decryption while in the middle of an FPGA configuration initiated by HPS, and the end result in this case is undefined.

5.3.5. Boot Handshake

There are two input signals from the FPGA to control HPS boot from the FPGA. Both are synchronized within the FPGA Manager. Boot software reads these signals before accessing a boot image in the FPGA. The following table describes the functionality of these signals.

Signal	Description
f2h_boot_from_fpga_on_failure	Indicates whether a fallback second-stage boot loader image is available in the FPGA on-chip RAM at memory location 0x0. The fallback second-stage boot loader image is used only if the HPS boot ROM does not find a valid second-stage boot loader image in the selected flash memory device.
f2h_boot_from_fpga_ready	<p>The f2h_boot_from_fpga_ready signal is used by the Boot ROM when accessing the public key stored in the FPGA. The Boot ROM will only use the signal if asserted to boot with the public key.</p> <p>Indicates a second-stage boot loader image is available in an FPGA on-chip RAM at memory location 0x0 and it is ready to be accessed.</p>

5.3.6. General Purpose I/O

Thirty-two general purpose inputs and thirty-two general purpose outputs are provided to the FPGA and are controlled through registers in the FPGA Manager.

No interrupts are generated through the input pins. All inputs are synchronized within the FPGA Manager. Output signals should be synchronized in the FPGA.

5.3.7. Clock

The FPGA manager has two clock input signals which are asynchronous to each other. The clock manager generates these two clocks:

- `cfg_clk`—the configuration slave interface clock input and also the `DCLK` output reference for FPGA configuration. Enable this clock in the clock manager only when configuration is active or when the configuration slave interface needs to respond to master requests.
- `l4_mp_clk`—the register slave interface clock.

Related Information

[Clock Manager](#) on page 56

5.3.8. Reset

The FPGA manager has the `fpga_manager_rst_n` reset signal. The reset manager drives this signal to the FPGA manager on a cold or warm reset. All distributed reset signals in the FPGA manager are asserted asynchronously at the same time and deasserted synchronously to their associated clocks.

Related Information

5.4.2.2. dclkcnt

Used to give software control in enabling DCLK at any time.

SW will need control of the DCLK in specific configuration and partial reconfiguration initialization steps to send spurious DCLKs required by the CB. SW takes ownership for DCLK during normal configuration, partial reconfiguration, error scenario handshakes including SEU CRC error during partial reconfiguration, SW early abort of partial reconfiguration, and initialization phase DCLK driving.

During initialization phase, a configuration image loaded into the FPGA can request that DCLK be used as the initialization phase clock instead of the default internal oscillator or optionally the CLKUSR pin. In the case that DCLK is requested, the DCLKCNT register is used by software to control DCLK during the initialization phase.

Software should poll the DCLKSTAT.DCNTDONE write one to clear register to be set when the correct number of DCLKs have completed. Software should clear DCLKSTAT.DCNTDONE before writing to the DCLKCNT register again.

This field only affects the FPGA if CTRL.EN is 1.

Module Instance	Base Address	Register Address
i_fpga_mgr_fpgamgrregs	0xFFD03000	0xFFD03008

Offset: 0x8

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
cnt RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cnt RW 0x0															

dclkcnt Fields

Bit	Name	Description	Access	Reset
31:0	cnt	Controls DCLK counter. Software writes a non-zero value into CNT and the FPGA Manager generates the specified number of DCLK pulses and decrements COUNT. This register will read back the original value written by software. Software can write CNT at any time.	RW	0x0

5.4.2.3. dclkstat

This write one to clear register indicates that the DCLKCNT has counted down to zero. The DCLKCNT is used by software to drive spurious DCLKs to the FPGA. Software will poll this bit after writing DCLKCNT to know when all of the DCLKs have been sent.

Module Instance	Base Address	Register Address
i_fpga_mgr_fpgamgrregs	0xFFD03000	0xFFD0300C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

												0x0	0x0	0x0	0x0

jtag_kick Fields

Bit	Name	Description	Access	Reset
3	clearRxFifo	A write 1 to this bit field will empty the RxFifo. A read will always return 0.	WO	0x0
2	clearTxFifo	A write 1 to this bit field will empty the TxFifo. A read will always return 0.	WO	0x0
1	stopSession	A write 1 to this bit field will kick off stop of an ongoing session of TX and RX. Please note that there should be atleast 1 word available in the Tx Fifo for this kick off to be successful. The status of this kick off can be read from status register SessionStatus field. stopSession has priority over startSession.	WO	0x0
0	startSession	A write 1 to this bit field will kick off a session of TX and RX. Please note that there should be atleast 1 word available in the Tx Fifo for this kick off to be successful. The status of this kick off can be read from status register SessionStatus field. stopSession has priority over startSession.	WO	0x0

5.4.2.18. jtag_data_w

A write to this field initiates a write to the TxFifo with the value provided. Please note that this is always a 32bit write, and lower 16 of these bits will be transferred over TDI and upper 16 of these bits will be transferred over TMS once the transfer is initiated. A write to this fifo when full will just be ignored. Also it is allowed to keep writing this fifo without actually initiating a transfer. A typical scenario where this is applicable is if the software want to keep a fixed number of bits ready for JTAG interface before kicking it off.

Both the fifos are 8 words deep. So you can have up to 128 bits buffered in the FIFOs. If you have more than 128 bits to be transferred, and want continuous transfer software should make sure proper data flow to avoid a Tx-Fifo under-run or Rx-Fifo over-run. A Rx-Fifo over-run will cause silent data loss, and a Tx-Fifo under-run will stop the transfer, and will stop the TCK toggles, till another transfer is initiated by software.

At 5MHz jtag clock $16 \times 100 / 5 = 320$ cycles of FPGA manager clock to transfer 1 word of data

At 25Mhz jtag clock $16 \times 100 / 25 = 64$ cycles of FPGA manager clock to transfer 1 word of data.

Module Instance	Base Address	Register Address

31:16	tmsData	Data to be transferred over TMS.	WO	0x0
15:0	tdiData		WO	0x0

5.4.2.19. jtag_data_r

A read to this field initiates a read to the RxFifo. Please note that the read always returns a 16 bit value. If the received number of bits are not aligned with 16, lower most n bits should be ignored by software. For example in the case of 6 bits received, rdata[15:10] will contain received bits and rdata[9:0] should be ignored. A read of the fifo while empty is not defined.

Both the fifos are 8 words deep. So you can have up to 128 bits buffered in the FIFOs. If you have more than 128 bits to be transferred, and want continuous transfer software should make sure proper data flow to avoid a Tx-Fifo under-run or Rx-Fifo over-run. A Rx-Fifo over-run will cause silent data loss, and a Tx-Fifo under-run will stop the transfer, and will stop the TCK toggles, till another transfer is initiated by software.
At 5Mhz jtag clock $16 \times 100 / 5 = 320$ cycles of FPGA manager clock to transfer 1 word of data
At 25Mhz jtag clock $16 \times 100 / 25 = 64$ cycles of FPGA manager clock to transfer 1 word of data.

5.4.2.22. imgcfg_ctrl_02

Allows HPS to control FPGA configuration.

The NCONFIGPULL, NSTATUSPULL, and CONFDONEPULL fields drive signals to the FPGA Control Block that are logically ORed into their respective pins. These signals are always driven independent of the value of EN. The polarity of the NCONFIGPULL, NSTATUSPULL, and CONFDONEPULL fields is inverted relative to their associated pins.

The MSEL (external pins), CDRATIO and CFGWDTH signals determine the mode of operation for Normal Configuration. For Partial Reconfiguration, CDRATIO is used to set the appropriate clock to data ratio, and CFGWDTH should always be set to 16-bit Passive Parallel.

AXICFGEN is used to enable transfer of configuration data by enabling or disabling DCLK during data transfers.

imgcfg_stat Fields

Bit	Name	Description	Access	Reset
29	emr	EMR valid bit	RO	0x0
28	jtagm	JTAG Master Session Status	RO	0x0
25	imgcfg_FifoFull	FifoFull Status of FPGA image configuration FIFO	RO	0x0
24	imgcfg_FifoEmpty	FifoEmpty Status of FPGA image configuration FIFO	RO	0x1
18	f2s_msel2	This read-only field allows software to observe the MSEL inputs from the device pins. The MSEL pins define the FPGA configuration mode. Please refer to CSS functional specifications for the exact definitions of MSEL encoding. In Arria 10 only 3 of these are used. Other bits will always read 0.	RO	0x0
17	f2s_msel1	This read-only field allows software to observe the MSEL inputs from the device pins. The MSEL pins define the FPGA configuration mode. Please refer to CSS functional specifications for the exact definitions of MSEL encoding. In Arria 10 only 3 of these are used. Other bits will always read 0.	RO	0x0
16	f2s_msel0	This read-only field allows software to observe the MSEL inputs from the device pins. The MSEL pins define the FPGA configuration mode. Please refer to CSS functional specifications for the exact definitions of MSEL encoding. In Arria 10 only 3 of these are used. Other bits will always read 0.	RO	0x0
13	f2s_nceo_oe	Chip select output enable driven from Control Subsystem.	RO	0x0
12	f2s_nconfig_pin	The value of this pin is used for monitoring purposes only in the FPGA manager.	RO	0x0
11	f2s_pr_error	Partial reconfiguration error	RO	0x0
10	f2s_pr_done	Partial reconfiguration done status	RO	0x0
9	f2s_pr_ready	Partial reconfiguration ready	RO	0x0
8	f2s_cvp_conf_done	Configuration via PCIe done indicator.	RO	0x0
continued...				

Bit	Name	Description	Access	Reset
7	f2s_condone_oe	This is the driven output enable of condone from the Control Subsystem (CSS). This signal can be used by software to determine the true status of the CSS.	RO	0x0
6	f2s_condone_pin	Sampled pin value for monitoring purposes only in FPGA manager. Please note that this value can be overridden by external devices.	RO	0x0
5	f2s_nstatus_oe	This is the driven output enable of nstatus from the Control Subsystem (CSS). This signal can be used by software to determine true status of the CSS.	RO	0x0
4	f2s_nstatus_pin	This status bit holds the signal value of nstatus which the Control Subsystem (CSS) sees when override is enabled, irrespective of what the pin value is. When this signal is 1, it doesn't affect the pin value. When this signal is 1, it pulls down the pin value (irrespective override enable).	RO	0x0
3	f2s_initdone_oe	This bit indicates the true status of the Control Subsystem.	RO	0x0
2	f2s_usermode	User mode status. Asserted only when FPGA has finally entered user mode. The FPGA manager receives this signal after a glitch filter external to FPGA manager. This glitch filtered signal is named fpga_config_complete.	RO	0x0
1	f2s_early_usermode	Status of early user mode signal from the Control Subsystem (CSS). Used by software to determine status of when HPS is configuring the shared IOs via sending POF to CSS.	RO	0x0
0	f2s_crc_error	CRC error indicator.	RO	0x0

5.4.2.24. intr_masked_status

When you read this register you read the active high pending interrupt status of corresponding bit.
This value is after the masking specified by intr_mask and after the polarity conversion as specified in intr_polarity

6. System Manager

The system manager in the hard processor system (HPS) contains memory-mapped control and status registers (CSRs) and logic to control system level functions as well as other modules in the HPS.

The system manager connects to the following modules in the HPS:

- Direct memory access (DMA) controller
- Ethernet media access controllers (EMAC0, EMAC1, and EMAC2)
- Error Checking and Correction Controller (ECC) for RAMs
- Microprocessor unit (MPU) subsystem
- NAND flash controller
- Secure Digital/MultiMediaCard (SD/MMC) controller
- Quad serial peripheral interface (SPI) flash controller
- USB 2.0 On-The-Go (OTG) controllers (USB0 and USB1)
- Watchdog timers

Related Information

For details on the document revision history of this chapter

6.1. Features of the System Manager

Software accesses the CSRs in the system manager to control and monitor various functions in other HPS modules that require external control signals. The system manager connects to these modules to perform the following functions:

- Sends pause signals to pause the watchdog timers when the processors in the MPU subsystem are in debug mode
- Selects the EMAC system interconnect master access options and other EMAC clock and interface options.
- Selects the SD/MMC controller clock options and system interconnect master access options.
- Selects the NAND flash controller bootstrap options and system interconnect master access option.
- Selects USB controller system interconnect master access option.
- Provides control over the DMA security settings when the HPS exits from reset.
- Provides boot source information that can be read during the boot process.
- Provides the capability to enable or disable an interface to the FPGA.

**ISO
9001:2008
Registered**

- Provides combined ECC status and interrupts from other HPS modules with ECC-protected RAM.
- Routes parity failure interrupts from the L1 caches to the Global Interrupt Controller.
- Provides the capability to inject errors during testing in the MPU L2 ECC-protected RAM.

6.2. System Manager Block Diagram and System Integration

The system manager connects to the level 4 (L4) bus through a slave interface. The CSRs connect to signals in the FPGA and other HPS modules.

Figure 15. System Manager Block Diagram

The system manager consists of the following:

- CSRs—Provide memory-mapped access to control signals and status for the following HPS modules:
 - EMACs
 - Debug core
 - SD/MMC controller
 - NAND controller
 - USB controllers
 - DMA controller
 - System interconnect
 - ECC memory interfaces for the following peripherals:
 - USB controllers
 - SD/MMC controller
 - Ethernet MACs
 - DMA controller
 - NAND flash controller
 - On-chip RAM
- Slave port interface—provides access to system manager CSRs for connected masters.
- Watchdog debug pause—accepts the debug mode status from the MPU subsystem and pauses the L4 watchdog timers.
- Reset Manager— system manager receives the reset signals from reset manager.

6.3. Functional Description of the System Manager

The system manager serves the following purposes:

- Provides software access to boot configuration and system information
- Provides software access to control and status signals in other HPS modules
- Provides combined ECC status and interrupt from other HPS modules with ECC-protected RAM
- Enables and disables HPS peripheral interfaces to the FPGA
- Provides eight registers that software can use to pass information between boot stages

6.3.1. Boot Configuration and System Information

The system manager provides boot configuration information through the `bootinfo` register. Sampled value of the HPS boot select (`BSEL`) pins are available to the Boot ROM software.

The boot source is determined by a combination of the `BSEL` pins and a fuse bit that can bypass the `BSEL` pins.

Related Information

[Booting and Configuration](#) on page 4634

6.3.2. Additional Module Control

Each module in the HPS has its own CSRs, providing access to the internal state of the module. The system manager provides registers for additional module control and monitoring. To fully control each module, you must program both the peripheral's CSR and its corresponding CSR in the System Manager. This section describes how to configure the system manager CS for each module.

6.3.2.1. DMA Controller

The security state of the DMA controller is controlled by the manager thread security (`mgr_ns`) and interrupt security (`irq_ns`) bits of the DMA register.

The `periph_ns` register bits determine if a peripheral request interface is secure or non-secure.

Note: The `periph_ns` register bits must be configured before the DMA is released from global reset.

Related Information

- [DMA Controller](#) on page 1969
- [System Manager Address Map and Register Definitions](#) on page 252

6.3.2.2. NAND Flash Controller

The bootstrap control register (`nand_bootstrap`) modifies the default behavior of the NAND flash controller after reset. The NAND flash controller samples the bootstrap control register bits when it comes out of reset.

The following `nand_bootstrap` register bits control configuration of the NAND flash controller:

- Bootstrap inhibit initialization bit (`noinit`)—inhibits the NAND flash controller from initializing when coming out of reset, and allows software to program all registers pertaining to device parameters such as page size and width.
- Bootstrap 512-byte device bit (`page512`)—informs the NAND flash controller that a NAND flash device with a 512-byte page size is connected to the system.
- Bootstrap inhibit load block 0 page 0 bit (`noloadb0p0`)—inhibits the NAND flash controller from loading page 0 of block 0 of the NAND flash device during the initialization procedure.
- Bootstrap two row address cycles bit (`tworowaddr`)—informs the NAND flash controller that only two row address cycles are required instead of the default three row address cycles.

You can use the system manager's `nanad_l3master` register to control the following signals:

- `ARPROT`
- `AWPROT`
- `ARDOMAIN`
- `AWDOMAIN`
- `ARCACHE`
- `AWCACHE`

These bits define the cache attributes for the master transactions of the DMA engine in the NAND controller.

Note: Register bits must be accessed only when the master interface is guaranteed to be in an inactive state.

Related Information

- [NAND Flash Controller](#) on page 1456
- [System Manager Address Map and Register Definitions](#) on page 252

6.3.2.3. EMAC

You can program the `emac_global` register to select either `emac_ptp_clk` from the Clock Manager or `f2s_ptp_ref_clk` from the FPGA fabric as the source of the IEEE 1588 reference clock for each EMAC.

You can use the system manager's `l3master` register to control the EMAC's `ARCACHE` and `AWCACHE` signals, by setting or clearing the (`arcache`, `awcache`) and (`arprot`, `awprot`) bits. These bits define the cache attributes for the master transactions of the DMA engine in the EMAC controllers.

Note: Register bits must be accessed only when the master interface is guaranteed to be in an inactive state.

The `phy_intf_sel` bit is programmed to select between a GMII (MII), RGMII or RMII PHY interface when the peripheral is released from reset. The `ptp_ref_sel` bit selects if the timestamp reference is internally or externally generated. The `ptp_ref_sel` bit must be set to the correct value before the EMAC core is pulled out of reset.

Note: EMAC0 must be set to internal timestamp.

Related Information

- [Clock Manager](#) on page 56
- [Ethernet Media Access Controller](#) on page 2066

6.3.2.4. USB 2.0 OTG Controller

The `usb*_l3master` registers in the system manager control the `HPROT` and `HAUSER` fields of the USB master port of the USB 2.0 OTG Controller.

Note: Register bits should be accessed only when the master interface is guaranteed to be in an inactive state.

Related Information

[USB 2.0 OTG Controller](#) on page 3031

6.3.2.5. SD/MMC Controller

The `sdmmc_l3master` register in the system manager controls the HPROT and HAUSER fields of the SD/MMC master port.

Note: Register bits should be accessed only when the master interface is guaranteed to be in an inactive state.

You can program software to select the clock's phase shift for `cclk_in_drv` and `cclk_in_sample` by setting the drive clock phase shift select (`drvsel`) and sample clock phase shift select (`smp1sel`) bits of the `sdmmc` register in the system manager.

Related Information

[SD/MMC Controller](#) on page 1685

6.3.2.6. Watchdog Timer

The system manager controls the watchdog timer behavior when the CPUs are in debug mode. The system manager sends a pause signal to the watchdog timers depending on the setting of the debug mode bits of the L4 watchdog debug register (`wddb0g`). Each watchdog timer built into the MPU subsystem is paused when its associated CPU enters debug mode.

Related Information

[Watchdog Timer](#) on page 4410

6.3.3. Boot ROM Code

Registers in the system manager control whether the boot ROM code configures the pin multiplexing for boot pins after a warm reset. Set the warm-reset-configure-pin-multiplex for boot pins bit (`warmrstcfgpinmux`) of the boot ROM code register to enable or disable this control.

Note: The boot ROM code always configures the pin multiplexing for boot pins after a cold reset.

Registers in the system manager also control whether the boot ROM code configures the I/O pins used during the boot process after a warm reset. Set the warm reset configure I/Os for boot pins bit (`warmrstcfgio`) of the `ctrl` register to enable or disable this control.

Note: By default, the boot ROM code always configures the I/O pins used by boot after a cold reset.

There can be up to four preloader images stored in flash memory. The (`initswlastld`) register contains the index of the preloader's last image that is loaded in the on-chip RAM.

The boot ROM software state register (`bootromswstate`) is a 32-bit general-purpose register reserved for the boot ROM.

The following warmram related registers are used to configure the warm reset from on-chip RAM feature and must be written by software prior to the warm reset occurring.

Table 55. The warmram Registers

Register	Name	Purpose
<code>enable</code>	Enable	Controls whether the boot ROM attempts to boot from the contents of the on-chip RAM on a warm reset.
<code>datastart</code>	Data start	Contains the byte offset of the warm boot CRC validation region in the on-chip RAM. The offset must be word-aligned to an integer multiple of four.
<code>length</code>	Length	Contains the length in bytes of the region in the on-chip RAM available for warm boot CRC validation.
<code>execution</code>	Execution address	Contains the global address the boot code jumps to in the on-chip RAM if the CRC validation succeeds.
<code>crc</code>	Expected CRC	Contains the expected CRC of the region in the on-chip RAM.

The number of wait states applied to the boot ROM's read operation is determined by the wait state bit (`waitstate`) of the `ctrl` register. After the boot process, software might require reading the code in the boot ROM. If software has changed the clock frequency of the `l3_main_clk` after reset, an additional wait state is necessary to access the boot ROM. Set the `waitstate` bit to add an additional wait state to the read access of the boot ROM. The enable safe mode warm reset update bit controls whether the wait state bit is updated during a warm reset.

6.3.3.1. Controlling the Boot Memory Map Through the System Interconnect

The System Manager contains a register, `noc_addr_remap_value`, that controls how the system interconnect maps memory addresses starting at 0x00000000. This register remaps the bottom of the memory map to either boot ROM or on-chip RAM.

Refer to "Address Remapping" in the System Interconnect chapter for details about using the `noc_addr_remap_value` register.

Related Information

[Address Remapping](#) on page 383

6.3.4. FPGA Interface Enables

The system manager can enable or disable interfaces between the FPGA and HPS.

The global interface bit (`intf`) of the global disable register (`gbl`) disables all interfaces between the FPGA and HPS.

Note: Ensure that the FPGA is configured before enabling the interfaces and that all interfaces between the FPGA and HPS are inactive before disabling them.

You can program the individual disable register (`indiv`) to disable the following interfaces between the FPGA and HPS:

You can program the FPGA interface enable registers (`fpgaintf_en_*`) to disable the following interfaces between the FPGA and HPS:

- Reset request interface
- JTAG enable interface
- I/O configuration interface
- Boundary scan interface
- Debug interface
- Trace interface
- System Trace Macrocell (STM) interface
- Cross-trigger interface (CTI)
- NAND interface
- SD/MMC interface
- SPI Master interface
- EMAC interfaces

6.3.5. ECC and Parity Control

The system manager can mask the ECC interrupts from each of the following HPS modules with ECC-protected RAM:

- MPU L2 cache data RAM
- On-chip RAM
- USB 2.0 OTG controller (USB0 and USB1) RAM
- EMAC (EMAC0, EMAC1, and EMAC2) RAM
- DMA controller RAM
- NAND flash controller RAM
- Quad SPI flash controller RAM
- SD/MMC controller RAM
- DDR interfaces

The system manager can inject single-bit or double-bit errors into the MPU L2 ECC memories for testing purposes. Set the bits in the appropriate memory enable register to inject errors. For example, to inject a single bit ECC error, set the `injs` bit of the `mpu_ctrl1_l2_eccregister`.

Note: The injection request is edge-sensitive, meaning that the request is latched on 0 to 1 transitions on the injection bit. The next time a write operation occurs, the data will be corrupted, containing either a single or double bit error as selected. When the data is read back, the ECC logic detects the single or double bit error appropriately. The injection request cannot be cancelled, and the number of injections is limited to once every five MPU cycles.

The system manager can also inject parity failures into the parity-protected RAM in the MPU L1 to test the parity failure interrupt handler. Set the bits of the parity fail injection register (`parityinj`) to inject parity failures.

Note: Injecting parity failures into the parity-protected RAM in the MPU L1 causes the interrupt to be raised immediately. There is no actual error injected and the data is not corrupted. Furthermore, there is no need for a memory operation to actually be performed for the interrupt to be raised.

6.3.6. Preloader Handoff Information

The system manager provides eight 32-bit registers to store handoff information between the preloader and the operating system. The preloader can store any information in these registers. These register contents have no impact on the state of the HPS hardware. When the operating system kernel boots, it retrieves the information by reading the preloader to OS handoff information register array. These registers are reset only by a cold reset.

6.3.7. Clocks

The system manager is driven by a clock generated by the clock manager.

Related Information

[Clock Manager](#) on page 56

6.3.8. Resets

The system manager receives two reset signals from the reset manager. The `sys_manager_rst_n` signal is driven on a cold or warm reset and the `sys_manager_cold_rst_n` signal is driven only on a cold reset. This function allows the system manager to reset some CSR fields on either a cold or warm reset and others only on a cold reset.

Related Information

31:0	rsv	Reserved for future use.	RO	0x0

6.4.1.4. wddbg

Controls the behavior of the L4 watchdogs when the CPUs are in debug mode. These control registers are used to drive the pause input signal of the L4 watchdogs. Note that the watchdogs built into the MPU automatically are paused when their associated CPU enters debug mode. Only reset by a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD06008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

6.4.1.6. mpu_ctrl_l2_ecc

This register is used to enable ECC on the L2 Data RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Some fields of this register are only reset by a cold reset (ignores warm reset). Some fields are affected by both warm and cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD06010

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

0	ecc_en	<div>Enable Single bit or Double bit error Detection and Single bit Error Correction for L2 Data RAM Only reset by a cold reset (ignores warm reset).</div>	RW	0x0						

6.4.1.7. dma

Registers used by the DMA Controller. All fields are reset by a cold or warm reset.
These register bits should be updated during system initialization prior to

removing the DMA controller from reset. They may not be changed dynamically during DMA operation.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD06020

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

6.4.1.24. noc_addr_remap_value

Address remap register. This register drives the remap bits for the NOC.
This is read / write register.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD06080

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														remap 1 0x0	remap 0 0x0

noc_addr_remap_value Fields

Bit	Name	Description	Access	Reset
1	remap1	<p>if this bit is 0 RAM is NOT available at base address 0x0000_0000</p> <p>if this bit is 1 RAM is also mapped to base address 0x0000_0000, as long as ROM is not being mapped to the same base address because of remap0</p> <p>Note: ROM is always available at base address 0xFFFC_0000 RAM is always available at base address 0xFFE0_0000</p>	RW	0x0
0	remap0	<p>if this bit is 0 ROM is also mapped to base address 0x0000_0000</p> <p>if this bit is 1 ROM is NOT available at base address 0x0000_0000</p> <p>Note: ROM is always available at base address 0xFFFC_0000 RAM is always available at base address 0xFFE0_0000</p>	RW	0x0

6.4.1.25. noc_addr_remap_set

This is a Write 1 to Set register.
Writing 0 is ignored, and writing 1 to a specific bit field sets the specific remap bit.
Reads should not return an error, but the actual read value is "Undefined" .

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD06084

Offset: 0x84

Access: WO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit	Name	Description	Access	Reset
1	remap1		WO	0x0
0	remap0		WO	0x0

6.4.1.26. noc_addr_remap_clear

This is a Write 1 to Clear register.
Writing 0 is ignored, and writing 1 to a specific bit field Clears the specific remap bit.
Reads should not return an error, but the actual read value is "Undefined" .

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD06088

Offset: 0x88

Access: WO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

6.4.1.32. mpu_status_l2_ecc

This is a read only register which reads the current mpu L2 ecc interrupt status.
A write to this register should return an error.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD060A4

Offset: 0xA4

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
merr_pending 0x0	Reserved			merr_info 0x0											
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
serr_pending 0x0	Reserved			serr_info 0x0											

mpu_status_l2_ecc Fields

Bit	Name	Description	Access	Reset
31	merr_pending	Unmaked value of a pending multiple bits ECC error status.	RO	0x0
27:16	merr_info	12 bit Serr Info field. In Baum this will be the index and way information where the ECC error occurred.	RO	0x0
15	serr_pending	Unmaked value of a pending single bit ECC error status.	RO	0x0
11:0	serr_info	12 bit Serr Info field. In Baum this will be the index and way information where the ECC error occurred.	RO	0x0

6.4.1.33. mpu_clear_l2_ecc

Write 1 to Clear register to clear the specific bit field of mpu l2 ecc interrupt pending status
Reads should not return an error, but the read value is undefined.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD060A8

Offset: 0xA8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
merr 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
serr 0x0	Reserved														

mpu_clear_l2_ecc Fields

Bit	Name	Description	Access	Reset
31	merr	Write 1 to this field to clear the MPU L2 ECC multiple bit Error interrupt Status and the actual Interrupt.	RW	0x0
15	serr	Write 1 to this field to clear the MPU L2 ECC single bit Error interrupt Status and the actual Interrupt.	RW	0x0

6.4.1.34. mpu_status_l1_parity

Parity status from L1 and scu. This is a read only register.
A write to this register should return an error.

[17] CPU1 SCU parity error
[16] CPU0 SCU parity error

[15] CPU1 BTAC parity error
[14] CPU1 GHB parity error
[13] CPU1 instruction tag RAM parity error
[12] CPU1 instruction data RAM parity error
[11] CPU1 main TLB parity error
[10] CPU1 data outer RAM parity error
[9] CPU1 data tag RAM parity error
[8] CPU1 data data RAM parity error.

[7] CPU0 BTAC parity error
[6] CPU0 GHB parity error
[5] CPU0 instruction tag RAM parity error
[4] CPU0 instruction data RAM parity error
[3] CPU0 main TLB parity error
[2] CPU0 data outer RAM parity error
[1] CPU0 data tag RAM parity error
[0] CPU0 data data RAM parity error.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD060AC

Offset: 0xAC

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

6.4.1.37. noc_timeout

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD060C0

Offset: 0xC0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															en 0x0

noc_timeout Fields

Bit	Name	Description	Access	Reset
0	en	NOC Timeout Enable. You can set this bit to enable an automatic timeout that flushes all pending transactions in the HPS-to-FPGA and lightweight HPS-to-FPGA bridges when they are shutdown and reset. To use this automatic timeout, the bridges must be operating above 100 MHz. The automatic timeout duration is approximately 320 ns. If your system application handles and completes all transactions before shutting down the bridges, this bit does not need to be enabled.	RW	0x0

6.4.1.38. noc_idlereq_set

Set IDLE request to each NOC master.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD060C4

Offset: 0xC4

Access: WO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

0	soc2fpga		not specified	0x0

6.4.1.41. noc_idleack

Idle acknowledge value from NOC Masters. This is asserted (value 1 in the field) in response to the IDLE requests asserted by software.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD060D0

Offset: 0xD0

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

6.4.2.4. romcode_qspi_reset_command

Information used by bootrom to send specific reset command sequences to QSPI.
This register value gets reset only on a cold reset.

Below are the definitions used by bootrom
0XXXXXXX00: Don't software reset.
0XXXXXXX01: Send 0x66, 0x99 as reset command.
0XXXXXXX02: Send 0xFF as reset command.
0XXXXXXX03: Send TBA as reset command.

There is also a custom command for devices we don't know about yet.
0XXXXZZZ81: Send byte 0xZZ as reset command.
0XXWWZZ82: Send byte 0xZZ, 0xWW as reset command.
0YYWWZZ83: Send byte 0xZZ, 0xWW, 0xYY as reset command.

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD06208 - 0xFFD06224

Offset: 0x8

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
value RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0x0															

romcode_qspi_reset_command Fields

Bit	Name	Description	Access	Reset
31:0	value	Address for CPU1 to start executing at after coming out of reset.	RW	0x0

6.4.2.5. romcode_initswstate

Initial Software loaded by the Boot ROM writes the magic value 0x49535756 (ISWV in ASCII) to this register when it has reached a valid state. Reset only on a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD0620C - 0xFFD06228

Offset: 0xC

Access: RW

Bit Fields

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														index RW 0x0	

romcode_initswlastId Fields

Bit	Name	Description	Access	Reset
1:0	index	Index of last image loaded.	RW	0x0

6.4.2.7. warmram_enable

Enables or disables the warm reset from On-chip RAM feature.
Reset only on a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD06218 - 0xFFD06234

Offset: 0x18

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
magic RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
magic RW 0x0															

warmram_enable Fields

Bit	Name	Description	Access	Reset
31:0	magic	Controls whether Boot ROM will attempt to boot from the contents of the On-chip RAM on a warm reset. When this feature is enabled, the Boot ROM code will not configure boot I/Os, the pin mux, or clocks. Note that the enable value is a 32-bit magic value (provided by the enum).	RW	0x0

Bit	Name	Description		Access	Reset						
		<table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>Boot ROM code will not attempt to boot from On-chip RAM on a warm reset</td></tr><tr><td>0xae9efebc</td><td>Boot ROM code will attempt to boot from On-chip RAM on a warm reset</td></tr></table>	Value	Description	0x0	Boot ROM code will not attempt to boot from On-chip RAM on a warm reset	0xae9efebc	Boot ROM code will attempt to boot from On-chip RAM on a warm reset			
Value	Description										
0x0	Boot ROM code will not attempt to boot from On-chip RAM on a warm reset										
0xae9efebc	Boot ROM code will attempt to boot from On-chip RAM on a warm reset										

6.4.2.8. warmram_datastart

Offset into On-chip RAM of the start of the region for CRC validation
Reset only on a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD0621C - 0xFFD06238

Offset: 0x1C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
offset RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
offset RW 0x0															

warmram_datastart Fields

Bit	Name	Description	Access	Reset
31:0	offset	Contains the byte offset into the On-chip RAM of the start of the On-chip RAM region for the warm boot CRC validation. The offset must be an integer multiple of 4 (i.e., aligned to a word). The Boot ROM code will set the top 16 bits to 0xFFFF and clear the bottom 2 bits.	RW	0x0

6.4.2.9. warmram_length

Length of region in On-chip RAM for CRC validation.
Reset only on a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD06220 - 0xFFD0623C

Offset: 0x20

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
size RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
size RW 0x0															

warmram_length Fields

Bit	Name	Description	Access	Reset
31:0	size	Contains the length (in bytes) of the region in the On-chip RAM for the warm boot CRC validation. If the length is 0, the Boot ROM won't perform CRC calculation and CRC check to avoid overhead caused by CRC validation. If the START + LENGTH exceeds the maximum offset into the On-chip RAM, the Boot ROM won't boot from the On-chip RAM. The length must be an integer multiple of 4. The Boot ROM code will clear the top 16 bits and the bottom 2 bits.	RW	0x0

6.4.2.10. warmram_execution

Offset into On-chip RAM to enter to on a warm boot.
Reset only on a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD06224 - 0xFFD06240

Offset: 0x24

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
offset RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
offset RW 0x0															

warmram_execution Fields

Bit	Name	Description	Access	Reset
31:0	offset	Contains the global address into the On-chip RAM that the Boot ROM jumps to if the CRC validation succeeds. This value is a logical address, not an offset from a base address.	RW	0x0

6.4.2.11. warmram_crc

Length of region in On-chip RAM for CRC validation.
Reset only on a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD06228 - 0xFFD06244

Offset: 0x28

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
expected RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
expected RW 0x0															

warmram_crc Fields

Bit	Name	Description	Access	Reset
31:0	expected	Contains the expected CRC of the region in the On-chip RAM. The Boot ROM code calculates the actual CRC for all bytes in the region specified by the DATA START and LENGTH registers. The contents of the EXECUTION register (after it has been read and modified by the Boot ROM code) is also included in the CRC calculation. The contents of the EXECUTION register is added to the CRC accumulator a byte at a time starting with the least significant byte. If the actual CRC doesn't match the expected CRC value in this register, the Boot ROM won't boot from the On-chip RAM. The CRC is a standard CRC32 with the polynomial: $x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$. There is no reflection of the bits and the initial value of the remainder is 0xFFFFFFFF and the final value is exclusive ORed with 0xFFFFFFFF.	RW	0x0

6.4.2.12. isw_handoff

These registers are used to store handoff information between the preloader and the OS. These 8 registers can be used to store any information. The contents of these registers have no impact on the state of the HPS hardware. A total of 8 x 32 bit registers for Second State Boot Loader handoff
Reset only on a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD06230 - 0xFFD0624C

Offset: 0x30 - 0x4C

Access: RW

7. SoC Security

Note:

For a complete NDA version of the entire Security SoC chapter, address map and register definitions, contact your local field sales office.

The Intel Arria 10 SoC provides the framework for implementing secure systems by offering a layered hardware and software solution. A dedicated Security Manager module in the Hard Processor System (HPS) supervises secure initialization of the SoC and manages system response during tamper events. User fuses offer secure boot options and registers within the Security Manager provide further enhancement of secure states. Using Elliptical Curve Digital Signal Algorithm (ECDSA256) with Secure Hash Algorithm (SHA256) and Advanced Encryption Standard (AES) algorithms in the FPGA's Configuration Subsystem (CSS), boot images can be authenticated and decrypted. The integration of the Arm TrustZone* technology and security firewalls within the Intel Arria 10 system interconnect provides defined partitioning in the device for secure and non-secure accesses. Protection mechanisms are integrated into debug components of the SoC to allow varying levels of visibility for debug.

7.1. Security Manager

The Security Manager module is integrated in the Hard Processor System (HPS) and provides the overall management of security within the SoC, including:

- Recognition of secure fuse configuration
- Secure state control and status check of security features
- Secure boot options
- Varying levels of debug visibility
- Anti-Tamper support

7.1.1. Security Manager Block Diagram

Figure 17. Security Manager Block Diagram

7.1.2. Functional Overview

The Security Manager integrates several functions that support the TrustZone technology, manage security states in the device, and hold secure fuse information.

The main components of the Security Manager architecture include:

- **Fuse Control (TEST):**
When the HPS is powered, the Security Manager ensures reliable and verified receipt of the fuse information from the Configuration Subsystem (CSS) in the FPGA, stores it in fuse shadow registers and can request further fuse information.
- **Security State and Status Check:**
This sub-module holds the security state of the system, which is controlled by the fuse bits, hardware and software programming. This sub-module also has the ability to check and raise the level of security.
- **Encryption Data Port:**
This interface receives authenticated and decrypted boot images from the CSS.
 - Support for ECDSA256 (SHA256) authenticated boot.
 - Support for AES-based encrypted boot.
- **Registers:**
 - Control Registers configure security state and debug options for the device.
 - Status and Error Registers flag transmission errors and interrupts.
 - Fuse Shadow Registers hold a copy of the user fuse information.
- **Anti-Tamper Control:**
On a tamper event, this module sends a signal to the Reset Manager to initiate the scrambling and clearing of all memories, including on-chip RAM, peripheral memories, L1 cache and L2 cache. Upon completion, the Security Manager sends a signal to the FPGA to indicate that the anti-tamper event has been handled.

7.1.3. Functional Description

7.1.3.1. Secure Initialization Overview

Secure initialization allows the device to boot and configure in a secured state.

Secure initialization begins with the CSS module. On FPGA power-up, the Configuration Subsystem (CSS) powers, initializes and loads the fuse bits. The CSS sends the FPGA its fuse configuration information. If the HPS is powered, the CSS sends the HPS fuse information to the Security Manager. This information is held in the `HPS_fusesec` shadow register in the Security Manager.

When the Security Manager is released from reset, it requests configuration information from the CSS and performs security checks. At this point, the rest of the HPS is still in reset. The security checks validate whether the state of each security option is valid. The Security Manager decodes the fuse bits and brings the rest of the HPS out of reset.

If there are errors in the initial transmission of the secure fuse information, the HPS stays in reset and no automatic retry occurs. Only an FPGA re-configuration causes a retry.

When the HPS is released from reset, the Security Manager sends signals to initialize the system blocks, such as the Clock Manager, FPGA Manager, System Manager. The clock control fuse information is automatically sent to the Clock Manager, the memory control fuse information is automatically sent to the Reset Manager and all other fuse functions (authentication, encryption, and public key source and length) are stored in a memory-mapped location for the boot ROM code to read. After these tasks are successfully completed, CPU0 comes out of reset in a secure state.

After CPU0 is released from reset, the boot ROM begins executing. At this time, the HPS is in a trusted state and the boot ROM code is guaranteed to execute as expected. For both secure and non-secure boot, all slave peripherals are brought out of reset in a secure state.

After initial security controls have been set, the boot ROM determines the second-stage boot loader source from the `bootinfo` register in the System Manager. The boot source can be from external memory through the HPS or through the FPGA. If the second-stage boot loader code comes from HPS external memory, then the boot ROM configures the clock and the interface to external memory.

When the boot ROM attempts to read from the flash, it looks for one of four images in external memory. Initially, it looks for image 0. If it is found, the image is authenticated, decrypted, or both depending on the requirements of the current security state. If these steps are successful, then the image is executed. However, if any of these steps fail, then the boot ROM moves onto the next image until it runs out of images.

For example, during a secure boot, the second-stage boot loader header includes an authentication key and the incoming image is authenticated. If indicated from the current security state, the image may be decrypted as well. The boot ROM contains functions to establish transitive trust to the second-stage boot code loaded from external flash or from the FPGA into on-chip RAM. If trust cannot be established in a secure boot, the HPS does not come out of reset and can attempt to load a different second-stage boot image.

For comprehensive information on the booting and boot image partitioning refer to the *Booting and Configuration* appendix of the *Arria 10 Hard Processor Technical Reference Manual*.

If all the images fail, it attempts to locate an image from the FPGA fabric and boot from there. If the FPGA boot fails, then it halts.

If the HPS receives its second-stage boot loader code from the FPGA, it waits for the FPGA to finish configuration before it obtains the image from FPGA RAM.

If required, a portion of the second-stage boot loader header can be used to raise security states of security features in the device that are currently in non-secure mode.

7.1.3.1.1. Secure Fuses

During initialization of the device, the Configuration Subsystem (CSS) sends the value of the HPS secure fuses to the HPS and holds a copy of the FPGA secure fuses. The HPS and FPGA each hold their own fuse values. However, a copy of these fuse values is held in the HPS_fusesec and fpga_fusesec registers within the Security Manager.

The following table details the HPS security fuse bits sent by the CSS to the Security Manager and contained within the HPS_fusesec register. A "blown" fuse state is represented by a 1 in the HPS_fusesec register and a "not blown" fuse state is represented by a 0.

Table 56. HPS_fusesec Register Description

Bits	Name	Description
31:27	Reserved	Bit values in this field are undefined.
26:23	csel_f	This field indicates the value of the clock select fuses that are available for configuring the clock for the boot interface and for the PLLs. Refer to the <i>Clock Configuration</i> section for more information on CSEL encodings.
22	dbg_access_f	This fuse determines the initial state of the debug access domains.
21	dbg_lock_JTAG	This field indicates if the HPS JTAG access level can be changed through software when the HPS is released from reset. <ul style="list-style-type: none"> 0x0= HPS JTAG access level can be changed through the sec_jtagdbg register. 0x1= HPS JTAG access level cannot be changed (locked).
20	dbg_lock_DAP	This field indicates if the DAP access level can be changed through software when the HPS is released from reset. <ul style="list-style-type: none"> 0x0= The DAP access level can be changed through the sec_dapdbg register. 0x1= The DAP access level cannot be changed (locked).
19	dbg_lock_CPU0	This field indicates if the CPU0 debug access level can be changed through software when the HPS is released from reset. <ul style="list-style-type: none"> 0x0= CPU0 debug access level can be changed through the sec_cpu0dbg register. 0x1= CPU0 debug access level cannot be changed (locked).
18	dbg_lock_CPU1	This field indicates if the CPU1 debug access level can be changed through software when the HPS is released from reset. <ul style="list-style-type: none"> 0x0= The CPU1 debug access level can be changed through the sec_cpu1dbg register. 0x1= The CPU1 debug access level cannot be changed (locked).
17	dbg_lock_CS	This field indicates if the CoreSight debug access level can be changed through software when the HPS is released from reset. <ul style="list-style-type: none"> 0x0= The CoreSight debug access level can be changed through the sec_csdbg register. 0x1= The CoreSight debug access level cannot be changed (locked).
continued...		

Bits	Name	Description
16	dbg_lock_FPGA	This field indicates if the FPGA debug access level can be changed through software when the HPS is released from reset. <ul style="list-style-type: none"> 0x0= The FPGA debug access level can be changed through the <code>sec_fpga_dbg</code> register. 0x1= The FPGA debug access level cannot be changed (locked).
15:12	Reserved	Bit values in this field are undefined.
11	clr_ram_order_f	This fuse value determines how RAMs are cleared during a tamper event. <ul style="list-style-type: none"> 0x0= All RAMs are cleared in parallel. 0x1= All RAMs are cleared in series.
10	clr_ram_cold_f	This fuse value indicates what happens to the RAM on a cold reset. <ul style="list-style-type: none"> 0x0= All RAMs are not cleared on a cold reset. 0x1= All RAMs are cleared on a cold reset.
9	clr_ram_warm_f	This fuse value indicates what happens to the RAMs on a warm reset. <ul style="list-style-type: none"> 0x0= All RAMs are not cleared on a warm reset. 0x1= All RAMs are cleared on a warm reset.
8	oc_boot_f	This fuse value determines if the second-stage boot code is allowed to boot from on-chip RAM. <ul style="list-style-type: none"> 0x0= Second-stage boot can be from on-chip RAM if enabled by the System Manager. 0x1= Second-stage boot is not from on-chip RAM.
7	hps_clk_f	This fuse value selects the clock used for the boot process and in the case of a tamper event, memory scrambling. <ul style="list-style-type: none"> 0x0= The external oscillator, <code>HPS_CLK1</code>, is used for boot. 0x1= The internal oscillator, <code>cb_intosc_ls_clk</code>, is used for boot.
6	fpga_boot_f	If blown, this fuse value allows the FPGA to configure independently and allows the HPS to boot from an encrypted next-stage boot source that was decrypted into the FPGA. <ul style="list-style-type: none"> 0x0= Booting is dependent on the BSEL pins. 0x1= HPS only boots from the FPGA; BSEL options are ignored and CSEL fuse options are ignored.
5	aes_en_f	This fuse value indicates if a decryption of the flash image is always performed. <ul style="list-style-type: none"> 0x0= An AES decryption of the flash image is determined from the second stage boot loader header. 0x1= An AES decryption of the flash image is always performed.
continued...		

Bits	Name	Description
4:2	kak_src_f	This bit field indicates the source of the Key Authorization Key (KAK) which can be in: <ul style="list-style-type: none"> Proprietary ROM FPGA logic elements User fuses
1	kak_len_f	This fuse value indicates the Key Authorization Key (KAK) length: <ul style="list-style-type: none"> 0x0= 256 bits 0x1= 384 bits
0	authen_en_f	This fuse value determines whether authentication of flash images is required prior to execution. <ul style="list-style-type: none"> 0x0= No authentication of the flash image is required prior to execution. 0x1= HPS authentication of all flash images is required prior to execution.

At initialization, the FPGA also receives fuse information that is pertinent to its configuration. The HPS can read this information through a secure serial interface, which shifts the FPGA fuse values into the `fpga_fusesec` register in the Security Manager. The CSS shifts in a 32-bit value although some of the bits are considered reserved.

- [Configuration, Design Security, and Remote System Upgrades in Arria 10 Devices](#)

7.1.3.2. Security State

The security state of the entire device is defined by the combination of the security state of the HPS and the FPGA. The initial security state of the device is determined by the fuse settings in the SoC. The values of these fuses are written to two shadow registers within the Security Manager: the `hps_fusesec` and the `fpga_fusesec` registers.

Each feature's security level can be increased from its initial fuse level through software, and for debug, through hardware as well. Changes to security level can only increase security and can never lower security. Both the HPS and FPGA have a mechanism to load security option bits as part of the second-stage boot loader and POF file, respectively, which can perform a check of the current security state and raise the security level.

7.1.3.2.1. Security Check

The Security Manager has the capability to perform security checks to identify discrepancies between the actual and expected security level so that measured actions can be taken through software and hardware if required.

There are three types of security checks that can be performed by the Security Manager:

- A fuse security level check
- A hardware access security level check
- A software access security level check

7.1.3.2.2. Secure Serial Interface

The HPS and FPGA communicate through a secure serial interface. The interface allows security of the HPS to be separate from the security of the FPGA. Software can initiate a request of the serial fuse interface via the Security Manager register.

7.1.3.3. Secure Debug

Debug logic in the Security Manager controls whether to enable or disable the JTAG, CPUs, Debug Access Port (DAP) and CoreSight domains. Debug access is determined by a combination of debug fuses, option bits, and registers that change the default state and set the functional state of debug peripherals.

During a power-on reset, access to all debug domains are prevented. During a warm reset, access to all debug domains except JTAG are prevented. Once a cold or warm reset is exited, the default debug access is defined by the value of the `dbg_disable_access` fuse and the `dbg_lock*` fuses. When the `dbg_disable_access` fuse is blown, HPS debug accesses to all domains are disabled by default out of reset. If the fuse is not blown, then the initial HPS debug state out of reset is enabled. To ensure that the device is brought up in a secure state, the `dbg_disable_access` fuse must be blown.

Related Information

- [ARM Debug Permissions](#)
Refer to this location for information on debug signals and permissions.
- [ARM Infocenter](#)
For more information about debug, refer to the ARM Cortex-A9 Technical Reference Manual.

7.1.3.3.1. MPU

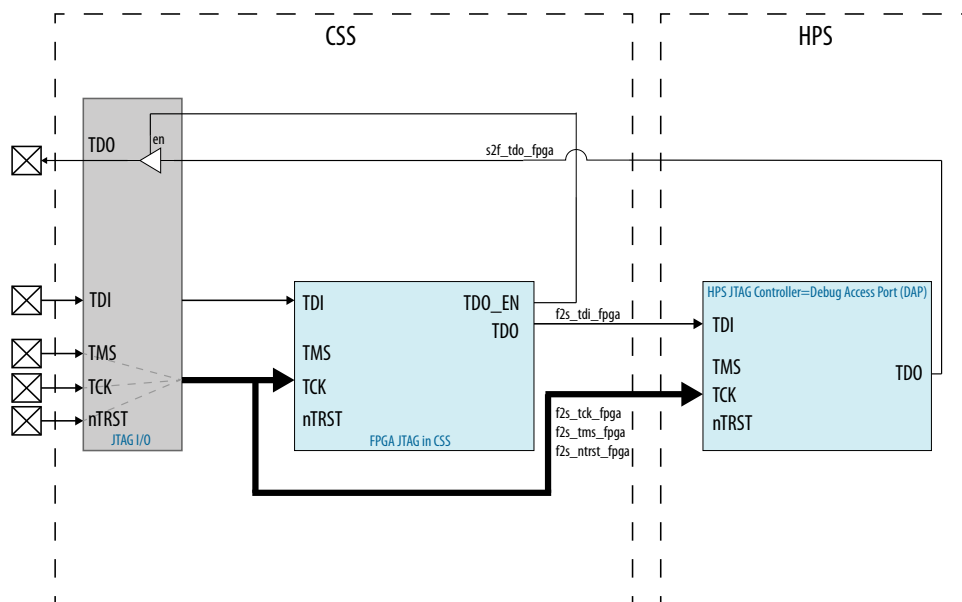

The MPU supports invasive and non-invasive debug. Invasive debug allows the user to control and observe the processor. Non-invasive debug allows you to observe the processor but not control it and is always available as part of invasive debug. The `NIDEN` and `SPNIDEN` signals are used for non-invasive debug in the MPU.

7.1.3.3.2. JTAG

The HPS and FPGA share a common set of JTAG pins and each have their own TAP controller which are chained together inside the device.

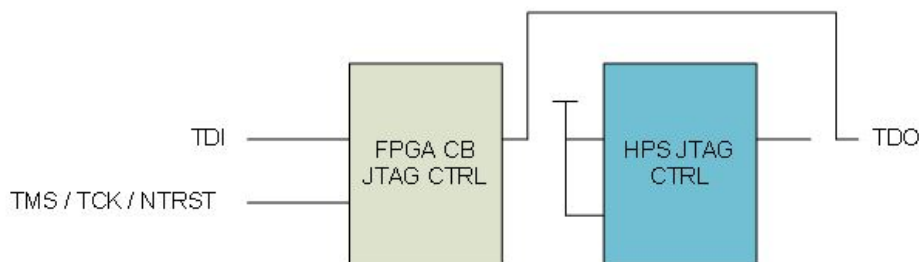

In the default JTAG configuration, the FPGA and HPS JTAG controllers are daisy-chained and controlled by an external JTAG port. The HPS JTAG controller is also referred to as the Debug Access Port.

Figure 18. JTAG Chaining

During power-on-reset, the JTAG and all debug domains are disabled. After the device is released from reset, the debug fuses are read by the Configuration Subsystem to determine if the external JTAG port or the JTAG controller to the FPGA or HPS is bypassed. Bypass can additionally be enabled through option bits in the Security Option registers discussed in the *Security State* section.

Figure 19. HPS JTAG Bypass

7.1.3.4. Reset Manager

To avoid unsecure snooping of RAM contents, the Security Manager can send signals to the Reset Manager to clear all RAM on a cold or warm reset.

These signals are the result of fuse programming combined with the configuration bits found in the HPS_Swoptset and HPS_secopt1 register in the Security Manager.

In addition, the fuse information that determines whether the RAMs are cleared in series or parallel is also sent to the Reset Manager. Clearing the memory in series prevents a power spike that could occur with parallel clearing of RAM. The policies for how or when security states take affect can be programmed in the HPS_secopt1 register. Refer to the "Security State" section for more information.

The RAM instances that are cleared during a warm or cold reset are:

- On-chip RAM
- USB0
- USB1
- SD/MMC
- EMAC0 RX and TX buffer
- EMAC1 RX and TX buffer
- EMAC2 RX and TX buffer
- DMA
- NAND read data, write data, and ECC RAMs
- QSPI
- MPU RAM

If a tamper event occurs, the Security Manager notifies the Reset Manager and the following sequence occurs:

1. All domain resets are asserted.
2. All RAMs are cleared.
3. The Reset Manager enters a dead state waiting for a POR release from Security Manager. All cold reset sources except Security Manager are ignored.

When FPGA POR and HPS POR are asserted, the Security Manager goes into reset.

For more information regarding Security States, refer to the "Security State" section.
- [Reset Manager](#) on page 138
For more information about reset, refer to the *Reset Manager* chapter.

7.1.3.5. Clock Configuration

Security Manager is driven by an internal oscillator, `cb_intosc_hs_clk`, in the Configuration Subsystem. This clock has wide variation across process and temperature. Once the Security Manager reads the fuse information, it drives the boot clock configuration to the Clock Manager. The Clock Manager samples the clock configuration on a cold and warm reset. If the `hps_clk_f` fuse is blown, the internal oscillator divided by 2, `cb_intosc_hs_div2_clk`, is used as the boot clock. If the fuse is not blown, an external oscillator is used. During boot ROM execution, the boot code configures the device clock based on the CSEL fuse settings or software code. The `cb_intosc_hs_div2_clk` can be considered the secure reference clock option.

The CSEL fuse settings have different meanings depending on how the `hps_clk_f` fuse is configured. When the `hps_clk_f` fuse is not blown, the external oscillator is the boot clock input.

Table 57. CSEL Encodings for hps_clk_f = 0

CSEL[3:0] Fuse Value	Description	MPU Clock Value
0x0	When no fuses are blown, the boot ROM returns clocks back to their default (bypass) boot mode and the CPU is driven by the external oscillator (HPS_CLK1), which must be in the range of 10 to 50 MHz. No PLL is enabled.	External Oscillator, HPS_CLK1 (10 to 50 MHz)
0x1	This encoding is typically used during a warm reset if you have already configured your clocks or PLL in the clock manager and would like to continue to use this configuration. If this encoding is selected, no changes are made to these settings and the clock configuration is essentially user selected. If this encoding is used during a power-on reset, then whatever the default reset values of the clocks are used.	User-selected clock source. Refer to the <i>Clock Manager</i> chapter for clock register settings.
0x2	Reserved	External Oscillator, HPS_CLK1 (10 to 50 MHz)
0x3	Reserved	External Oscillator, HPS_CLK1 (10 to 50 MHz)
0x4	Reserved	External Oscillator, HPS_CLK1 (10 to 50 MHz)
0x5	Reserved	External Oscillator, HPS_CLK1 (10 to 50 MHz)
0x6	Reserved	External Oscillator, HPS_CLK1 (10 to 50 MHz)
0x7	External oscillator input clock, HPS_CLK1, is in the range of 10 to 15 MHz	533 to 800Mhz
0x8	External oscillator input clock, HPS_CLK1, is in the range 15 to 20 MHz.	600 to 800Mhz
0x9	External oscillator input clock, HPS_CLK1, is in the range 20 to 25 MHz.	640 to 800Mhz
0xA	External oscillator input clock, HPS_CLK1, is in the range 25 to 30 MHz.	666 to 800Mhz
0xB	External oscillator input clock, HPS_CLK1, is in the range 30 to 35 MHz.	685 to 800Mhz
0xC	External oscillator input clock, HPS_CLK1, is in the range 35 to 40 MHz.	700 to 800Mhz
<i>continued...</i>		

CSEL[3:0] Fuse Value	Description	MPU Clock Value
0xD	External oscillator input clock, HPS_CLK1, is in the range 40 to 45 MHz.	711 to 800Mhz
0xE	External oscillator input clock, HPS_CLK1, is in the range 45 to 50 MHz.	720 to 800Mhz
0xF	The boot ROM returns clocks back to their default (bypass) boot mode and the CPU is driven by the external oscillator (HPS_CLK1). No PLL is enabled.	External Oscillator, HPS_CLK1 (10 to 50 MHz)

Table 58. CSEL Encodings for hps_clk_f = 1

CSEL[3:0] Fuse Value	Description	MPU Clock Value
0x0	Bypass mode; in this mode all clocks are reset and boot mode is ensured active; cb_intosc_hs_div2_clk (cb_intosc_hs clock divided by 2) is used.	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x1	This encoding is typically used during a warm reset if you have already configured your clocks or PLL in the Clock Manager and would like to continue to use this configuration. If this is encoding is selected, no changes are made to these settings and the clock configuration is essentially user selected. If this is encoding is used during a power-on reset, then whatever the default reset values of the clocks are used.	User-selected clock source. Refer to the <i>Clock Manager</i> chapter for clock register settings.
0x2	PLL is used with the internal oscillator (30 to 100 MHz)	120 to 800 MHz
0x3	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x4	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x5	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x6	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x7	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x8	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x9	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0xA	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0xB	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
<i>continued...</i>		

CSEL[3:0] Fuse Value	Description	MPU Clock Value
0xC	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0xD	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0xE	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0xF	Bypass mode; reset all clocks and ensure boot mode is active; cb_intosc_hs_div2_clk is used.	cb_intosc_hs_div2_clk (60 to 200 MHz)

For more information regarding the CSEL encodings and descriptions, please refer to the *Bootling and Configuration* Appendix.

7.1.3.6. FPGA Security Features

The FPGA has several security fuses which can control the following functions:

- Limiting acceptance of only encrypted and authenticated POFs
- Disabling partial reconfiguration and scrubbing
- Disabling test access
- Disabling external configuration
- Limiting JTAG access
- Bypassing HPS or FPGA JTAG
- Locking or disabling the battery-backed volatile key
- Disabling the OTP key

Note that there is a fuse sent to the FPGA CSS, called hps_jtag_bypass, which performs the same function of removing the HPS from the JTAG chain. However, this fuse is a permanent disable, whereas using software to program the sec_jtagdbg register has the same affect, but may be changed later by software.

7.1.3.7. Secure Boot

No ordering of boot or FPGA configuration is required because the FPGA and HPS may be brought up in any order, and they can both raise the security level of the entire device at any time before user code is loaded to execute.

The SoC may securely boot in one of three ways:

1. The HPS boot and FPGA configuration occur separately.
2. The HPS boots from the FPGA after the FPGA is configured
3. The HPS boots first and configures the FPGA.

Note: The device has the capability to execute standard non-secure boot in any of these three ways, as well. In this section, only secure booting mechanisms are reviewed.

Note: The FPGA must be powered on for the HPS to come out of reset properly.

Related Information

[Bootting and Configuration](#) on page 4634

For more information about the boot process refer to the *Bootting and Configuration* appendix.

7.1.3.7.1. Boot Configuration

Bootting configuration is provided from a combination of the BSEL pins and the boot mode fuses. The BSEL pins indicate if the boot source is the FPGA or one of the HPS flash interfaces. If the `fpga_boot_f` fuse is blown, it overrides these pin values. The `fpga_boot_f` fuse value can be read from the `hps_fusesec` register.

Table 59. BOOTSEL Field Values and Flash Device Selection

BOOTSEL Field Value	Flash Device
0x0	Reserved
0x1	FPGA (HPS-to-FPGA bridge)
0x2	1.8 V NAND flash memory
0x3	3.0 V NAND flash memory
0x4	1.8 V SD/MMC flash memory with external transceiver
0x5	3.0 V SD/MMC flash memory with internal transceiver
0x6	1.8 V quad SPI flash memory
0x7	3.0 V quad SPI flash memory

Within the device, there are fuses that provide some of the boot mode configuration information. The fuse values can be read through the HPS_fusesec register:

Table 60. HPS_fusesec Register Description

Bits	Name	Description
31:27	Reserved	Bit values in this field are undefined.
26:23	csel_f	This field indicates the value of the clock select fuses that are available for configuring the clock for the boot interface and for the PLLs. Refer to the <i>Clock Configuration</i> section for more information on CSEL encodings.
22	dbg_access_f	This fuse determines the initial state of the debug access domains.
21	dbg_lock_JTAG	This field indicates if the HPS JTAG access level can be changed through software when the HPS is released from reset. <ul style="list-style-type: none"> 0x0= HPS JTAG access level can be changed through the sec_jtagdbg register. 0x1= HPS JTAG access level cannot be changed (locked).
20	dbg_lock_DAP	This field indicates if the DAP access level can be changed through software when the HPS is released from reset. <ul style="list-style-type: none"> 0x0= The DAP access level can be changed through the sec_dapdbg register. 0x1= The DAP access level cannot be changed (locked).
19	dbg_lock_CPU0	This field indicates if the CPU0 debug access level can be changed through software when the HPS is released from reset. <ul style="list-style-type: none"> 0x0= CPU0 debug access level can be changed through the sec_cpu0dbg register. 0x1= CPU0 debug access level cannot be changed (locked).
18	dbg_lock_CPU1	This field indicates if the CPU1 debug access level can be changed through software when the HPS is released from reset. <ul style="list-style-type: none"> 0x0= The CPU1 debug access level can be changed through the sec_cpu1dbg register. 0x1= The CPU1 debug access level cannot be changed (locked).
17	dbg_lock_CS	This field indicates if the CoreSight debug access level can be changed through software when the HPS is released from reset. <ul style="list-style-type: none"> 0x0= The CoreSight debug access level can be changed through the sec_csdbg register. 0x1= The CoreSight debug access level cannot be changed (locked).
16	dbg_lock_FPGA	This field indicates if the FPGA debug access level can be changed through software when the HPS is released from reset. <ul style="list-style-type: none"> 0x0= The FPGA debug access level can be changed through the sec_fpgadb register. 0x1= The FPGA debug access level cannot be changed (locked).
15:12	Reserved	Bit values in this field are undefined.
continued...		

Bits	Name	Description
11	clr_ram_order_f	This fuse value determines how RAMs are cleared during a tamper event. <ul style="list-style-type: none"> 0x0= All RAMs are cleared in parallel. 0x1= All RAMs are cleared in series.
10	clr_ram_cold_f	This fuse value indicates what happens to the RAM on a cold reset. <ul style="list-style-type: none"> 0x0= All RAMs are not cleared on a cold reset. 0x1= All RAMs are cleared on a cold reset.
9	clr_ram_warm_f	This fuse value indicates what happens to the RAMs on a warm reset. <ul style="list-style-type: none"> 0x0= All RAMs are not cleared on a warm reset. 0x1= All RAMs are cleared on a warm reset.
8	oc_boot_f	This fuse value determines if the second-stage boot code is allowed to boot from on-chip RAM. <ul style="list-style-type: none"> 0x0= Second-stage boot can be from on-chip RAM if enabled by the System Manager. 0x1= Second-stage boot is not from on-chip RAM.
7	hps_clk_f	This fuse value selects the clock used for the boot process and in the case of a tamper event, memory scrambling. <ul style="list-style-type: none"> 0x0= The external oscillator, HPS_CLK1, is used for boot. 0x1= The internal oscillator, cb_intosc_ls_clk, is used for boot.
6	fpga_boot_f	If blown, this fuse value allows the FPGA to configure independently and allows the HPS to boot from an encrypted next-stage boot source that was decrypted into the FPGA. <ul style="list-style-type: none"> 0x0= Booting is dependent on the BSEL pins. 0x1= HPS only boots from the FPGA; BSEL options are ignored and CSEL fuse options are ignored.
5	aes_en_f	This fuse value indicates if a decryption of the flash image is always performed. <ul style="list-style-type: none"> 0x0= An AES decryption of the flash image is determined from the second stage boot loader header. 0x1= An AES decryption of the flash image is always performed.
4:2	kak_src_f	This bit field indicates the source of the Key Authorization Key (KAK) which can be in: <ul style="list-style-type: none"> Proprietary ROM FPGA logic elements User fuses
1	kak_len_f	This fuse value indicates the Key Authorization Key (KAK) length: <ul style="list-style-type: none"> 0x0= 256 bits 0x1= 384 bits
0	authen_en_f	This fuse value determines whether authentication of flash images is required prior to execution. <ul style="list-style-type: none"> 0x0= No authentication of the flash image is required prior to execution. 0x1= HPS authentication of all flash images is required prior to execution.

7.1.3.7.2. Secure Boot Process

Secure boot allows the HPS to release from reset into a known state and then validate the authenticity and integrity of the second-stage boot loader code prior to executing it. Secure boot ensures that only authorized code is executed on the system. In addition, the system has the option to configure the FPGA from the HPS, which provides a secure boot mechanism for the FPGA portion of the SoC. In this mode, the HPS boot code can authenticate the FPGA POF prior to loading it.

The HPS and FPGA can also be booted securely but independently, with the HPS executing authenticated and decrypted user code out of external RAM and the FPGA receiving an encrypted FOP configuration file by enabling an FPGA configuration source through the MSEL pins.

Boot ROM code runs on CPU0 and CPU1 is held in reset. Once control passes to the second-stage boot loader, CPU1 can be released from reset.

7.1.3.7.3. Authentication and Decryption

Authentication is provided for the second-stage boot loader code and both the HPS and FPGA can utilize the AES algorithms in the Configuration Subsystem (CSS) to decrypt boot images and POF files, respectively.

Three levels of boot are available to the device:

- Authentication only: The second-stage boot loader code is not encrypted, but there are public key signatures attached to the image and the code only executes if all of the signatures pass. ECDSA256 (SHA 256) is used for authenticated boot.
- Decryption only: The user boot code is encrypted and must be decrypted before execution. AES-based algorithms in the FPGA are used for decryption.
- Authentication and Decryption: The user boot code is encrypted and signed.

If authentication and decryption are enabled, the data is first authenticated and then decrypted using the AES algorithms. Authentication is performed using the public key authorization key (KAK) held in the user fuses. The KAK can be 256 bits. The KAK public key authentication fuses are lockable by the user in groups of 64 bits or less.

The Security Manager's `hps_fusesec` register can be read to identify the source of the public (root) key used for authentication of the second-stage boot loader. The source of the public (root) key can be one of the following:

- External software
- ROM
- FPGA logic elements
- User Access Fuses (UAF)

AES decryption algorithms are available through the FPGA CSS and are enabled prior to decryption through a combination of user fuses and software programming. Elliptic curve cryptographic algorithms are used in an authenticated boot. Decrypted data is sent to the Security Manager to be read by the CPU or DMA.

The FPGA has higher priority in the CSS, and the FPGA AES algorithms abort decryption and authentication of data if the FPGA starts configuration or reconfiguration.

7.1.3.8. Anti-Tamper

The Security Manager receives a tamper detection signal when a tamper event is detected in the device.

Anti-tamper logic can be implemented in the FPGA soft logic to detect a tamper event. No tamper detection is available until the FPGA is configured. The user must define the anti-tamper design. Some examples of tamper detection that could be implemented are:

- Using the FPGA voltage sensor to detect any IR drops across the device.
- Using an A/D controller to detect temperature changes in the device due to tamper.
- Assigning loaner I/O as dedicated tamper pins to detect package break-away.

The tamper detection signal sent to the Security Manager, `anti_tamper_in`, is an active low signal. When there is no tamper event, it is driven to 1. The Security Manager also provides a tamper acknowledge signal to the FPGA interface. The tamper event input to the HPS is gated with a signal indicating the completion of FPGA configuration. This prevents an inadvertent tamper event assertion or tamper response from the HPS to the rest of the system.

When the Security Manager receives a tamper detection assertion, it prepares the system to go into reset and notifies the Reset Manager of the event. When the Reset Manager receives the tamper event assertion from the Security Manager, it drives all the peripherals and MPU into reset. It asserts a request and enables all peripherals memories to initiate a memory scramble and a memory clear, either in series or parallel, depending on the information sent from the Security Manager. The memory clearing includes the on-chip RAM, peripheral memories, L1 caches, and L2 cache. Once the memory scramble and clear completes, each module sends an acknowledgment back to the Reset Manager.

Upon completion of memory scrambling of all IPs, the Security Manager sends a response to the FPGA indicating that a tamper event has been handled in the HPS. This response is followed by HPS entering into a cold reset without exiting until another power cycle occurs. Both Security Manager and Reset Manager enter reset. Other resets, such as warm reset or cold reset, do not affect the state of the Security Manager or the Reset Manager.

If the FPGA POR is de-asserted while the HPS is in a tamper event reset, then the Security Manager goes back to the reset state.

7.2. Security System Extensions

Beyond the Security Manager module, other secure features can be implemented at a system level within the SoC.

7.2.1. TrustZone

The Cortex-A9 MPU subsystem has integrated TrustZone technology, which provides a system solution to protect application platforms from malicious attack. The TrustZone hardware and supporting software are designed to provide a strong security solution regardless of the operating environment. TrustZone creates a separation between the secure and non-secure areas of the SoC and allows the designer to choose which assets in a design are designated as secure and non-secure.

TrustZone security is implemented in the Cortex-A9 MPU subsystem in three ways:

- Hardware partitioning through the implementation of firewalls: Resources can be assigned and identified as secure or non-secure.
- Virtual processor execution: Each core can context switch between secure and non-secure operation.
- Secure debug control: Both secure and non-secure hardware debug exist and the type of debug allowed can be configured by the user.

7.2.1.1. Secure Partitioning

System interconnect and cache accesses as well as processor execution can be securely partitioned using the TrustZone infrastructure.

7.2.1.1.1. Secure Bus Accesses

The Cortex-A9 MPCore and other masters that utilize the system interconnect can be configured for secure or non-secure accesses.

Master accesses drive a protection signal, `AxPROT[1]`, to communicate the security level of the attempted transaction. The Cortex-A9 drives this signal low for secure accesses and high for non-secure accesses. The secure firewalls determine whether the access is allowed or not. A slave access type defaults to secure if no other configuration is programmed. Users can define whether a bus error is generated or if a bus failure occurs when a secure access is violated.

Note: Secure processor configuration is programmed through the CP15 register.

Related Information

For more detailed information about secure bus accesses, refer to the "Secure Firewall" section.
- [SoC Security](#) on page 332
For more information about SoC Security, refer to the *SoC Security* Chapter.

7.2.1.1.2. Secure Cache Accesses

Secure and non-secure partitioning also extends to the L1 and L2 caches.

There is a 32-bit physical address space for secure and non-secure transactions and a 33rd bit is provided to indicate security. The cache is able to store both secure and non-secure lines.

The Accelerator Coherency Port (ACP) in the ArmCortex-A9 MPCore can be used with TrustZone technology. The security state of the masters using the ACP must be the same as the Cortex-A9 processor.

For more information about SoC Security, refer to the *SoC Security* Chapter.

7.2.1.2. Virtual Processor Operation

Two virtual processors (secure and non-secure) with context switch capability (monitor mode) exist for each Cortex-A9 processor core. The secure virtual processor only accesses secure resources and the non-secure virtual processor only accesses non-secure resources.

Figure 20. Virtual Processor Environment with Monitor Mode

A context switch to secure operation is achieved through a secure monitor call (SMC) instruction or the following hardware exceptions (if configured to do so):

- IRQ interrupt
- Faster Interrupt Request (FIQ) interrupt
- External data abort
- External prefetch abort

When a context switch occurs, the state of the current mode is saved and restored on the next context switch or on a return from exception.

Exception Vector Tables

Three exception vector tables are provided for the MPU with TrustZone:

1. Non-secure
2. Secure
3. Monitor mode

Typically IRQs are used for non-secure interrupts and FIQs are used for secure interrupts. The location of each of the three vector tables can be moved at runtime.

The Generic Interrupt Controller (GIC) can handle secure and non-secure interrupts and prevent non-secure accesses from reading or modifying the configuration of a secure interrupt. An interrupt can be made secure by programming the appropriate bits in the Interrupt Security Register. Secure interrupts are always given a higher priority than non-secure interrupts.

7.2.2. Arria 10 HPS Secure Firewalls

You can use the system interconnect firewalls to enforce security policies for slave and memory regions in the system interconnect.

The firewalls support the following features:

- Secure or non-secure access configurable per peripheral
- Privileged or user access configurable for some peripherals
- Per-transaction security

Each firewall contains the security configuration registers (SCRs) that set security policies and define which transactions are allowed to go through the firewall. If you want to generate an error any time a transaction is blocked in the firewall, then you must set the `error_response` bit in the `global` register of the `noc_fw_ddr_l3_ddr_scr` module at base address 0xFFD13400. If this bit is clear, transactions blocked by the firewall return random data.

Note: Future devices may not support the return of random data and may only support an error response for blocked firewall transactions. For designs that may be ported to future devices, Intel recommends you to set the `error_response` bit in the `global` register.

There are five main firewalls in the HPS:

- Peripheral
- System
- HPS-to-FPGA
- On-Chip RAM
- SDRAM (which includes DDR and DDR L3 firewalls)

Figure 24. On-Chip RAM Firewall

Up to six regions of the on-chip RAM can be partitioned for non-secure accesses.

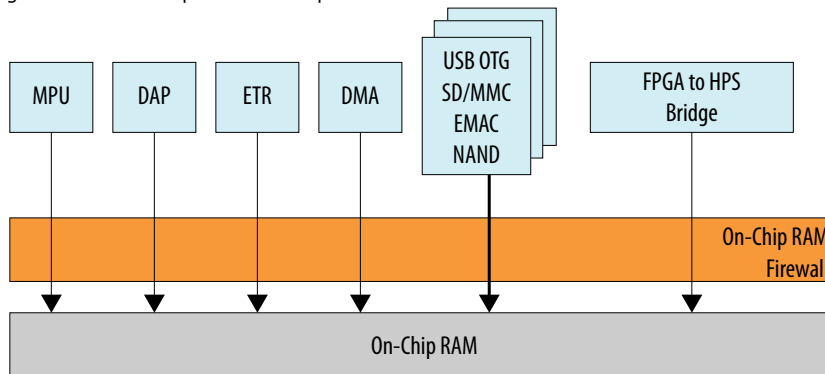

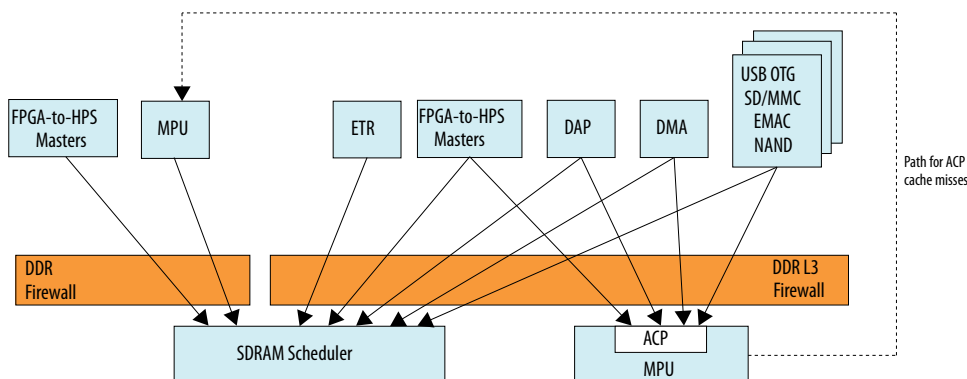

Figure 25. SDRAM firewall

Transactions from the DMA, ETR, DAP, FPGA-to-HPS masters or HPS masters (USB, SD/MMC, EMAC, NAND) are routed to either the ACP or the SDRAM scheduler depending on the cacheable bit. Only cacheable transactions are routed to the ACP, with non-cacheable transactions being routed directly to the SDRAM scheduler. If an access to the ACP results in a cache miss in the L1 and L2 cache systems, then the MPU master M1 issues a transaction to the SDRAM scheduler. Only cacheable transactions go through to the ACP. If a cache miss occurs on the ACP cycle, then the MPU masters a new transaction to the SDRAM scheduler. Accesses from the MPU or FPGA-to-SOC masters that are tightly coupled to the MPU go through the DDR firewall only.

Note:

The dotted line in the diagram represents the path taken when an ACP access occurs and misses in the L1 and L2 cache.

7.2.2.2. Secure Transaction Protection

The interconnect provides two levels of transaction protection.

The two levels of transaction protection are:

- Security Firewalls:

Security firewalls enforce the Secure World read and write transactions. The term "security firewall" and "firewall" may be used interchangeably within the context of this section.

- Privilege filter

The privilege filter leverages the firewall mechanism and provides additional filtering by allowing control of the privilege level of L4 slave transactions. The privilege filter applies to writes only.

All slaves on the SoC are placed behind a security firewall. A subset of slaves are also placed behind a privilege filter. Transactions to these slaves pass through two firewall structures as shown in the figure below. The transaction packet must pass both a security firewall and the privilege filter to reach the slave. A transaction error causes random data or a slave error depending on where the transaction failed and how the `error_response` bit in the `global` register of the `noc_fw_ddr_l3_ddr_scr` module is programmed.

Note: Future devices may not support the return of random data and may only support an error response for blocked firewall transactions. For designs that may be ported to future devices, Intel recommends you to set the `error_response` bit in the `global` register.

Figure 26. Successful Secure Transaction Path

Each firewall has an associated firewall register which can be programmed by the DAP, FPGA fabric or MPU in secure mode only. A subset of the L4 slaves can additionally be programmed to configure their privilege filter policy.

7.2.2.2.1. Peripheral and System Firewalls

The peripheral and system firewalls each have a group of Security Configuration Registers (SCRs) that can be programmed by the DAP, FPGA fabric or MPU only in secure mode.

The peripheral and system firewalls can be configured by programming the security bits in the SCR blocks. Each slave has an SCR containing a security bit for each available master, which enables a different security access level to be programmed for each master-slave pair. At reset, all accesses are configured to be secure. When a master-slave security bit is 0, only secure packets are allowed to pass the firewall and reach the intended target. When the master-slave security bit is 1, the firewall passes the transaction.

Table 65. Security Bit Value

Secure Flag Value	Access
0	Only secure packets are allowed to pass the firewall.
1	Transaction packets are allowed to pass the firewall.

When a transaction packet is sent from a master, the master also drives a secure flag signal on the bus. This flag indicates whether the attempted transaction from the master is secure or non-secure. For AXI master accesses, this flag is the `~AxPROT[1]` signal.

For L4 ECC, L4 system or L4 DDR master accesses, this flag is the `MSecure[0]` signal.

When the flag signal is driven high, it indicates a secure access. When the flag signal is low, it indicates a non-secure access.

Secure Transaction Example

A successful secure access attempt by a master, depends on the security bit configuration in the Security Control Register and the value of the master secure flag sent by the master.

All SoC transactions are set to secure out of reset with a return of random data when transactions are blocked. If you want an error response returned for blocked transactions, you must set the `error_response` bit in the `global` register of the `noc_fw_ddr_l3_ddr_scr` module at base address `0xFFD13400`. If this bit is clear, transactions blocked by the firewall return random data.

Note: Future devices may not support the return of random data and may only support an error response for blocked firewall transactions. For designs that may be ported to future devices, Intel recommends you to set the `error_response` bit in the `global` register.

To initiate a secure transaction:

1. The master drives the address of the slave as well as the master secure flag signal, indicating that the access is intended to be secure.
2. The firewall compares the programmed security bit of the master-slave peripheral pair to the master secure flag signal to determine if the access is valid.
3. If the access is valid, the transaction passes to the next level. If the access is not valid, random data is fed back to the master.

Table 66. Peripheral and System Transaction Results

Security Bit in Firewall Register	Master Secure Flag	Transaction Pass/Fail	Transaction Type
0	0	No	None (Blocked transaction)
0	1	Yes	Secure
1	0	Yes	Non-secure
1	1	Yes	Secure

Non-secure Transaction Configuration

When the SoC is released from reset, only secure transactions are allowed through the firewalls. The user must configure any master-slave pairs that are required to be non-secure.

The SCR registers must be accessed in secure mode to configure the firewall access to non-secure.

1. After the SoC is released from reset, the MPU, FPGA2SOC masters or the DAP accesses the required Security Configuration Register (SCR) by executing a secure write. The peripheral firewall SCR registers are within the `soc_noc_fw_l4_per` register group and the system firewall SCR registers are found within the `soc_noc_fw_l4_sys` register group.
2. To configure the slave to allow a non-secure access by a master, set the corresponding security bit to 1.

The configured master is able to successfully execute a non-secure read or write to the configured slave.

7.2.2.2.2. HPS-to-FPGA Firewall

The HPS-to-FPGA firewall is used to filter access to all the FPGA, including the HPS-to-FPGA bridge and the lightweight HPS-to-FPGA bridge.

The secure firewall for the HPS-to-FPGA can be disabled by programming the `lwsoc2fpga` register and `soc2fpga` register within the `noc_fw_soc2fpga` group.

7.2.2.2.3. On-Chip RAM Firewall

At reset all memories are secure. Out of reset, regions of memories can be configured for non-secure accesses.

The on-chip RAM is divided into six regions, where the granularity of the address boundary is 4 KB. Within each region, a non-secure or shared memory region can be assigned by programming a `base` and `limit` value in the corresponding `regionNAddr` register, with `N` denoting the region number. Each of these regions can be enabled by writing to the `enable` register or setting the corresponding bit in the `enable_set` register.

When an incoming transaction falls within any enabled non-secure regions, the firewall allows both secure and non-secure packets. When the transaction is outside of any enabled regions, the firewall only allows secure packets.

When a transaction packet is sent from a master, the master also drives a secure master flag signal on the bus. This flag indicates whether the attempted transaction from the master is for a secure or non-secure memory region. When the flag signal is driven high, it indicates a secure access. When the flag signal is low it indicates a non-secure access.

On-Chip RAM Transaction Configuration

Because all memories are secure when they exit reset, the on-chip RAM Security Control Register block must be configured by a secure master before non-secure or shared memory accesses are allowed.

1. Configure the `base` and `limit` fields of the `regionNaddr` register, where `N` denotes the region number.
2. Enable the non-secure memory region by setting the corresponding `regionNenable` bit in the `enable_set` register, where `N` denotes the region number.

7.2.2.2.4. SDRAM Firewall

Two SDRAM firewalls are implemented to allow a different security policy depending on the master.

One firewall filters accesses from the MPU and the FPGA-to-SDRAM interface. The other firewall filters accesses from all other masters on the HPS and applies the same security policy to both coherent and non-coherent accesses. Both firewalls are logically and physically split within the interconnect.

The SDRAM Firewall supports a minimum region size of 64 KB. Each master is allowed a different number of firewall regions:

- The MPU can have up to four firewall regions.
- The FPGA-to-SDRAM interface can have up to twelve firewall regions.
- Any HPS bus master can have up to eight firewall regions.

7.2.2.3. Privilege Filter

If a transaction packet has passed the security firewall, it may pass through a privilege filter. The privilege filter only applies to writes. All reads are passed without exception.

The privilege filter decodes the incoming user or privilege accesses and determines whether to pass or fail the transaction. It is separate from the security firewall and transactions generally carry both privilege and secure bits. The privilege filters are configured in the interconnect by executing a read-modify-write to the `l4_priv` register or setting individual bits in the `l4_set` register. If a privilege bit is set, both privilege and user mode transactions are allowed to the slave. If a privilege bit is cleared using the `l4_clear` register, then only privileged transactions are allowed to the slave.

The following slaves can be programmed using the privilege registers in the interconnect module:

- HPS-to-FPGA bridge
- Lightweight HPS-to-FPGA bridge
- UARTs
- SP Timers
- I2C Modules
- GPIO
- SD/MMC

- QSPI
- EMAC Modules
- SPI
- Secure and non-secure DMA
- USB
- NAND Controller

The following table shows the result of privileged and user master accesses based on the value of the programmed privilege bit for a particular slave.

Note: All read accesses pass regardless of the privilege bit value.

Table 67. Privilege Filter Transaction

Read/Write	Privilege Signal	Privilege bit	Transaction Pass/Fail
Read	0	0	Pass
	0	1	Pass
	1	0	Pass
	1	1	Pass
Write	0	0	Fail
	0	1	Pass
	1	0	Pass
	1	1	Pass

7.2.2.4. Master Security Policy

Each master has an inherent security transaction capability.

Masters accessing slaves can be configured to one of three different security policies:

- Per transaction: The master is capable of generating secure and non-secure transactions.
- Secure: The master only supplies secure transactions.
- Non-secure: The master only generates non-secure transactions.

At reset, all accesses default to secure transactions. The table below details the transaction capability of each master within the SoC. Some masters are only capable of non-secure transactions.

Table 68. Master Transaction Capability

Master	Transaction Capability
DMA	Secure/Non-secure
DAP	Secure/Non-secure
USB OTG 0/1	Non-secure
SD/MMC	Non-secure
EMAC0/1/2	Secure/Non-secure
<i>continued...</i>	

Master	Transaction Capability
NAND	Non-secure
FPGA-to HPS Bridge	Secure/Non-secure
ETR	Secure/Non-secure
MPU	Secure/Non-secure
FPGA-to-SDRAM	Secure/Non-secure

Security policies are based on secure and privilege attributes. For instance, if CPU0 is configured to access NAND registers in both secure and non-secure mode and CPU0 attempts an access when the core is in secure or non-secure mode, no error occurs. However, if CPU0 is allowed to access NAND registers only in secure mode and CPU0 is operating in non-secure mode, then CPU0 receives an error response when accessing the NAND registers. If both the security firewall and privilege firewall are implemented, security firewall filters all of the accesses. If an access fails, random data or an error response is sent to the master, depending on how the `error_response` bit in the `global` register of the `noc_fw_ddr_l3_ddr_scr` module is programmed. If access is granted by the security firewall, then the transaction enters the privilege firewall. If access is granted, the request enters the peripheral IP.

Note: Future devices may not support the return of random data and may only support an error response for blocked firewall transactions. For designs that may be ported to future devices, Intel recommends you to set the `error_response` bit in the `global` register.

7.2.2.5. Secure Interconnect Reset

When the SoC is released from reset, every slave on the interconnect is in the secure state (boot secure).

The only masters capable of secure accesses out of reset are:

- MPU
- DAP
- HPS-to-FPGA fabric

8. System Interconnect

The components of the hard processor system (HPS) communicate with one another, and with other portions of the SoC device, through the system interconnect. The system interconnect consists of the following blocks:

- The main level 3 (L3) interconnect
- The SDRAM L3 interconnect
- The level 4 (L4) buses

The system interconnect is the main communication bus for the MPU and all IPs in the SoC device.

The system interconnect is implemented by the Arteris FlexNoC network-on-chip (NoC) interconnect module.

The system interconnect supports the following features:

- An L3 interconnect that provides high-bandwidth routing between masters and slaves in the HPS
- SDRAM L3 interconnect, providing access to a hard memory controller in the FPGA fabric through a multiport front end (MPFE) scheduler for sharing the external SDRAM between multiple masters in the SoC device
- Independent L4 buses running in several clock domains. These buses handle data traffic for low- to mid-level bandwidth slave peripherals and accesses to peripheral control and status registers throughout the address map.
- On-chip debugging and tracing capabilities
- Security firewalls with the following capabilities:
 - Secure or nonsecure access configured per peripheral
 - Privileged or user access configured per peripheral (for some peripherals)
 - Security optionally configured per transaction at the master
- Quality of service (QoS) with three programmable levels of service on a per-master basis

8.1. About the System Interconnect

8.1.1. Features of the System Interconnect

The system interconnect supports high-throughput peripheral devices. The system interconnect has the following characteristics:

- Byte oriented address handling
- Data bus width up to 128 bits
- Arm TrustZone-compliant firewall and security support, with additional security features configurable per master
- Programmable quality-of-service (QoS) optimization
- Dedicated SDRAM L3 interconnect, providing access and scheduling for the hard memory controller in the FPGA portion of the SoC device
- On-chip debug and tracing capabilities
- Multiple independent L4 buses with independent clock domains and protocols

The L4 buses are each connected to a master in the main L3 interconnect for control and status register access. Each L4 bus is 32 bits wide and is connected to multiple slaves. The L4 buses also provide a low- to mid-level tier of the system interconnect for lower-bandwidth slave peripherals. Each L4 bus is 32 bits wide and operates in a separate clock domain.

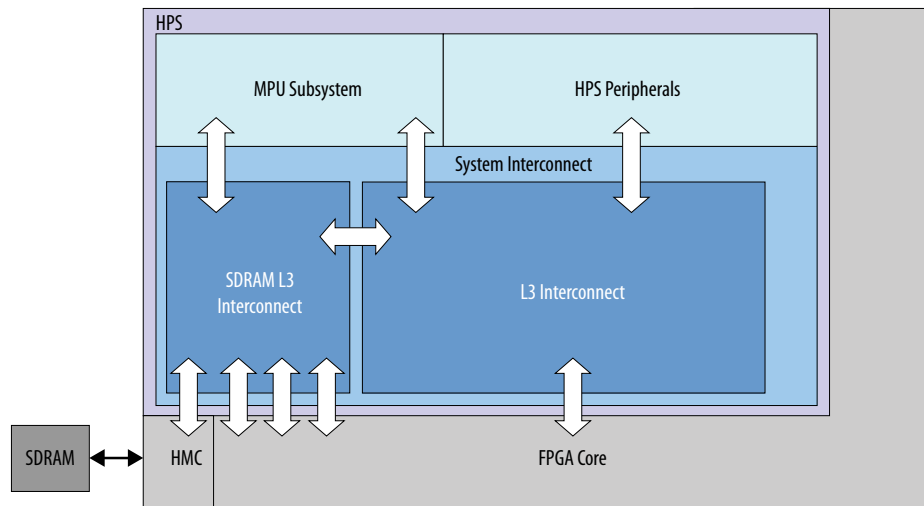

8.1.2. Block Diagram and System Integration

8.1.2.1. System Interconnect Block Diagram

The following figures show the system interconnect, including the main L3 interconnect, SDRAM L3 interconnect, and L4 buses.

Figure 27. High-Level System Interconnect Block Diagram

The following figure shows the relationships among the system interconnect and other major SoC components.

8.1.2.3. System Interconnect Architecture

The system interconnect has a transaction-based architecture that functions as a partially-connected fabric. Not all masters can access all slaves.

The system interconnect is a packet-oriented network on chip (NoC), in which each packet carries a transaction between a master and a slave. The interconnect provides interface widths up to 128 bits, connecting to the L4 slave buses and to HPS and FPGA masters and slaves.

The system interconnect provides low-latency connectivity to the following bridges:

- HPS-to-FPGA bridge
- Lightweight HPS-to-FPGA bridge
- FPGA-to-HPS bridge
- Three FPGA-to-SDRAM ports

8.1.2.3.1. SDRAM L3 Interconnect Architecture

The SDRAM L3 interconnect provides access to the hard memory controller in the FPGA portion of the SoC device.

The SDRAM L3 interconnect is part of the system interconnect, and includes these components:

- SDRAM scheduler
- SDRAM adapter

The SDRAM L3 interconnect operates in a clock domain that is 1/2 the speed of the hard memory controller clock.

8.1.3. Arria 10 HPS Secure Firewalls

You can use the system interconnect firewalls to enforce security policies for slave and memory regions in the system interconnect.

The firewalls support the following features:

- Secure or non-secure access configurable per peripheral
- Privileged or user access configurable for some peripherals
- Per-transaction security

Each firewall contains the security configuration registers (SCRs) that set security policies and define which transactions are allowed to go through the firewall. If you want to generate an error any time a transaction is blocked in the firewall, then you must set the `error_response` bit in the `global` register of the `noc_fw_ddr_l3_ddr_scr` module at base address 0xFFD13400. If this bit is clear, transactions blocked by the firewall return random data.

Note: Future devices may not support the return of random data and may only support an error response for blocked firewall transactions. For designs that may be ported to future devices, Intel recommends you to set the `error_response` bit in the `global` register.

There are five main firewalls in the HPS:

- Peripheral
- System
- HPS-to-FPGA
- On-Chip RAM
- SDRAM (which includes DDR and DDR L3 firewalls)

8.1.4. About the Rate Adapters

The L3 interconnect contains a rate adapter wherever a low-bandwidth channel transfers data to a high-bandwidth channel.

Related Information

[Functional Description of the Rate Adapters](#) on page 389

8.1.5. About the SDRAM L3 Interconnect

The hard processor system (HPS) provides a specialized SDRAM L3 Interconnect dedicated to SDRAM accesses.

The SDRAM L3 Interconnect contains an SDRAM scheduler and an SDRAM adapter. The SDRAM scheduler functions as a multi-port front end (MPFE) for multiple HPS masters. The SDRAM adapter is responsible for connecting the HPS to the SDRAM hard memory controller in the FPGA portion of the device. The SDRAM L3 interconnect is part of the system interconnect.

8.1.5.1. Features of the SDRAM L3 Interconnect

The SDRAM L3 interconnect supports the following features:

- Connectivity to the SDRAM hard memory controller supporting:
 - DDR4-SDRAM
 - DDR3-SDRAM
- Integrated SDRAM scheduler, functioning as a multi-port front end (MPFE)
- Configurable SDRAM device data widths
 - 16-bit, with or without 8-bit error-correcting code (ECC)
 - 32-bit, with or without 8-bit ECC
 - 64-bit, with or without 8-bit ECC
- High-performance ports
 - MPU subsystem port
 - Main L3 interconnect port
 - Three FPGA ports
 - Two 32-, 64-, or 128-bit ports
 - One 32- or 64-bit port
 - Firewall and security support port

Note: At system startup, the SDRAM I/O pins can be configured separately from the FPGA fabric, allowing the SoC HPS to boot before any soft logic is configured in the FPGA.

8.1.5.2. SDRAM L3 Interconnect Block Diagram and System Integration

The SDRAM L3 interconnect is composed of two main blocks: SDRAM adapter and SDRAM scheduler.

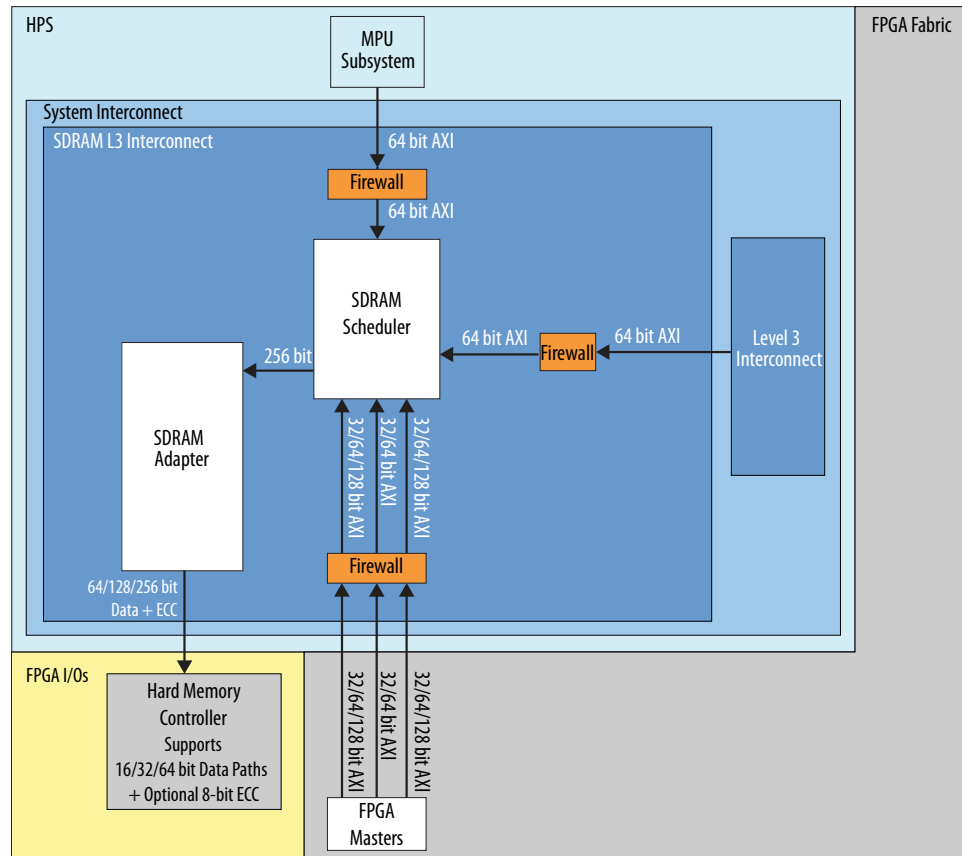

The SDRAM adapter is responsible for bridging the hard memory controller in the FPGA fabric to the SDRAM scheduler. The adapter is also responsible for ECC generation and checking.

The ECC register interface provides control to perform memory and ECC logic diagnostics.

The SDRAM scheduler is an MPFE, responsible for arbitrating collisions and optimizing performance in traffic to the SDRAM controller in the FPGA portion of the device.

Three Arm Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) ports are exposed to the FPGA fabric, allowing soft logic masters to access the SDRAM controller through the same scheduler unit as the MPU subsystem and other masters within the HPS. The MPU has access to the SDRAM adapter's control interface to the hard memory controller.

Figure 34. SDRAM L3 Interconnect Block Diagram

The hard memory controller in the FPGA portion of the device has a dedicated connection to the SDRAM L3 interconnect. This connection allows the hard memory controller to become operational before the rest of the FPGA has been configured.

8.1.5.3. About the SDRAM Scheduler

The SDRAM scheduler functions as a multi-port front end (MPFE), scheduling transactions from multiple masters to the SDRAM.

The SDRAM scheduler supports the following masters:

- The MPU
- The L3 system interconnect
- The FPGA-to-SDRAM bridges

The SDRAM scheduler arbitrates among transactions initiated by the masters, and determines the order of operations. The scheduler arbitrates among the masters, ensuring optimal interconnect performance based on configurable quality-of-service settings.

The SDRAM scheduler can be configured through the registers.

Related Information

- [Functional Description of the QoS Generators](#) on page 396
Detailed description of the system interconnect's quality-of-service features
- [Arbitration and Quality of Service in the SDRAM Scheduler](#) on page 392

8.1.6. About Arbitration and Quality of Service

When multiple transactions need the same interconnect resource at the same time, arbitration logic resolves the contention. The quality-of-service (QoS) logic gives you control over how the contention is resolved.

Arbitration and QoS logic work together to enable optimal performance in your system. For example, by setting QoS parameters, you can prevent one master from using up the interconnect's bandwidth at the expense of other masters.

The system interconnect supports QoS optimization through programmable QoS generators. The QoS generators are located on interconnect initiators, which correspond to master interfaces. The initiators insert packets into the interconnect, with each packet carrying a transaction between a master and a slave. Each QoS generator creates control signals that prioritize the handling of individual transactions to meet performance requirements.

Arbitration and QoS in the HPS system interconnect are based on the following concepts:

- **Priority**—Each packet has a priority value. The arbitration logic generally gives resources to packets with higher priorities.
- **Urgency**—Each master has an urgency value. When it initiates a packet, it assigns a priority equal to its urgency.
- **Pressure**—Each data path has a pressure value. If the pressure is raised, packets on that path are treated as if their priority was also raised.
- **Hurry**—Each master has a hurry value. If the hurry is raised, all packets from that master are treated as if their priority was also raised.

Proper QoS settings depend on your performance requirements for each component and peripheral, and for system performance as a whole. Intel recommends that you become familiar with QoS optimization techniques before you try to change the QoS settings in the HPS system interconnect.

Related Information

- [Arria 10 HPS Master-to-Slave Connectivity Matrix](#) on page 366
- [Functional Description of the QoS Generators](#) on page 396
- [Configuring the Quality of Service Logic](#) on page 405

8.1.7. About the Service Network

The service network is physically separate from the NoC datapath.

Through the service network, you can perform these tasks:

- Access internal interconnect registers
- Update master and slave peripheral security features

8.1.8. About the Observation Network

The observation network connects probes to the CoreSight trace funnel through the debug channel. It is physically separate from the NoC datapath.

The observation network connects probes to the observer, which is a port in the CoreSight trace funnel. Through the observation network, you can perform these tasks:

- Enable error logging
- Selectively trace transactions in the system interconnect
- Collect HPS transaction statistics and profiling data

The observation network consists of probes in key locations in the interconnect, plus connections to observers. The observation network works across multiple clock domains, and implements its own clock crossing and pipelining where needed.

The observation network sends probe data to the CoreSight subsystem through the ATB interface. Software can enable probes and retrieve probe data through the interconnect observation registers.

Related Information

[Functional Description of the Observation Network](#) on page 400

8.2. Functional Description of the System Interconnect

The system interconnect provides access to a 4 GB address space.

Address spaces are divided into one or more nonoverlapping contiguous regions.

Figure 35. HPS Address Space Relationships

Positions of HPS address spaces. For readability, some memory regions are shown out-of-scale to their addresses.

The window regions provide access to other address spaces. The thin black arrows indicate which address space is accessed by a window region (arrows point to accessed address space).

The following table shows the base address and size of each region that is common to the L3 and MPU address spaces.

Table 69. Common Address Space Regions

Region Name	Description	Base Address	Size
FPGASLAVES	FPGA slaves	0xC0000000	960 MB
PERIPH	Peripheral	0xFC000000	64 MB
LWFGASLAVES ⁽⁸⁾	Lightweight FPGA slaves	0xFF200000	2 MB

Related Information

[Arria 10 HPS Available Address Maps](#) on page 377

Details of the L3 and MPU address maps

⁽⁸⁾ The LWFGASLAVES region is part of the "PERIPH" region.

8.2.1. System Interconnect Address Spaces

The system interconnect supports multiple address spaces.

Each address space uses some or all of the 4 GB address range. The address spaces overlap. Depending on the configuration, different address spaces are visible in different regions for each master.

The following address spaces are available:

- The L3 address space
- The MPU address space
- The SDRAM address space

8.2.1.1. Arria 10 HPS Available Address Maps

The following figure shows the default system interconnect address maps for all masters. The figure is not to scale.

Figure 36. Address Maps for System Interconnect Masters

	DMA	Master Peripherals (4)	DAP	FPGA-to-HPS Bridge	MPU

0x00000000					Boot ROM or OCR (3)

Notes on Address Maps

- (1) Transactions on these addresses are directly decoded by the SCU and L2 cache.
- (2) The MPU accesses SDRAM through a dedicated port to the SDRAM scheduler. The SDRAM window size also depends on L2 cache filtering.

(3) This region can be configured to access on-chip RAM, by using the `noc_addr_remap_value`, `noc_addr_remap_set`, and `noc_addr_remap_clear` registers, in the system manager.

(4) The following peripherals can master the interconnect:

- Ethernet MACs
- USB-2.0 OTG controllers
- NAND controller
- ETR
- SD/MMC controller

For the MPU L3 master, either the boot ROM or on-chip RAM can map to address 0x0 and obscure the lowest 128 KB or 256 KB of SDRAM.

At boot time, the MPU does not have access to the SDRAM address space from the top of ROM or on-chip RAM to 0x00100000. This is because the MPU's SDRAM access is controlled by the MPU L2 filter registers, which only have a granularity of 1 MB. After booting completes, the MPU can change address filtering to use the lowest 1 MB of SDRAM.

For non-MPU masters, either the on-chip RAM or the SDRAM maps to address 0x0. When mapped to address 0x0, the on-chip RAM obscures the lowest 256 KB of SDRAM for non-MPU masters.

8.2.1.2. Arria 10 HPS L3 Address Space

The Arria 10 HPS L3 address space is 4 GB and applies to all L3 masters except the MPU subsystem.

The system interconnect `noc_addr_remap_value`, `noc_addr_remap_set`, and `noc_addr_remap_clear` registers, in the System Manager, determine if the address space starting at address 0x0 is mapped to the on-chip RAM (256 KB) or the SDRAM. SDRAM is mapped to address 0x0 on reset.

The L3 address space configurations contain the regions shown in the following table:

Table 70. L3 Address Space Regions

Description	Condition	Base Address	End Address	Size
SDRAM window (without on-chip RAM)	remap0 set, remap1 clear ⁽⁹⁾	0x00000000	0xBFFFFFFF	3 GB
On-chip RAM (low mapping)	remap0 set, remap1 set ⁽⁹⁾	0x00000000	0x0003FFFF	256 KB
SDRAM window (with on-chip RAM)	remap0 set, remap1 set ⁽⁹⁾	0x00040000	0xBFFFFFFF	3145471 KB = 3 GB - 256 KB
HPS-to-FPGA	Not visible to FPGA-to-HPS bridge.	0xC0000000	0xFBFFFFFF	960 MB
System trace macrocell	Always visible to DMA and FPGA-to-HPS	0xFC000000	0xFEFFFFFF	48 KB
Debug access port	Not visible to master peripherals. Always visible to other masters.	0xFF000000	0xFF1FFFFF	2 MB
Lightweight HPS-to-FPGA	Not visible to master peripherals. Always visible to other masters.	0xFF200000	0xFF3FFFFF	2 MB
Peripherals	Not visible to master peripherals. Always visible to other masters.	0xFF800000	0xFFFDFFFF	8064 KB
On-chip RAM (high mapping)	Always visible	0xFFE00000	0xFFFE3FFF	256 KB

The boot ROM and internal MPU registers (SCU and L2) are not accessible to L3 masters.

Cache coherent memory accesses have the same view of memory as the MPU.

SDRAM Window Region

The SDRAM window region is 3 GB and provides access to the bottom 3 GB of the SDRAM address space.

On-Chip RAM Region, Low Mapping

The system interconnect `noc_addr_remap_value` register determines if the 256 KB starting at address 0x0 is mapped to the on-chip RAM or the SDRAM. The SDRAM is mapped to address 0x0 on reset.

HPS-to-FPGA Slaves Region

The HPS-to-FPGA slaves region provides access to 960 MB of slaves in the FPGA fabric through the HPS-to-FPGA bridge.

Lightweight HPS-to-FPGA Slaves Region

The lightweight HPS-to-FPGA slaves provide access to slaves in the FPGA fabric through the lightweight HPS-to-FPGA bridge.

Peripherals Region

The peripherals region includes slaves connected to the L3 interconnect and L4 buses.

⁽⁹⁾ For details about the `noc_addr_remap_value` register, refer to "Memory Map Remap Bits"

On-Chip RAM Region, High Mapping

The on-chip RAM is always mapped (independent of the boot region contents).

Related Information

- [Memory Map Remap Bits](#) on page 384
Details of how to map ROM and RAM to 0x00000000

More information about L3 address space mapping is in the *Introduction to the Hard Processor System* chapter.
- [Cortex-A9 Microprocessor Unit Subsystem](#) on page 1022
For general information about the MPU subsystem, refer to the *Cortex-A9 Microprocessor Unit Subsystem* chapter.

8.2.1.3. MPU Address Space

The MPU address space is 4 GB and applies to MPU masters.

Addresses generated by the MPU are decoded in three ways:

- By default, MPU accesses to locations between 0x100000 (1 MB) to 0xC0000000 (3 GB) are made to the SDRAM controller.
- Addresses in the SCU and L2 register region (0xFFFFC000 to 0xFFFFFFFF) are the SCU and L2 bus.
- Accesses to all other locations are made to the L3 interconnect.

The MPU L2 cache controller contains a master connected to the main L3 interconnect and a master connected to the SDRAM L3 interconnect.

The system interconnect `noc_addr_remap_value`, `noc_addr_remap_set`, and `noc_addr_remap_clear` registers, in the System Manager, determine if the address space starting at address 0x0 is mapped to the on-chip RAM (256 KB) or the ROM (128 KB). The ROM is mapped to address 0x0 on reset.

The MPU address space contains the following regions:

Table 71. MPU Default Address Space Regions

Description	Condition	Base Address	End Address	Size
Boot ROM	<code>remap0</code> clear, <code>remap1</code> clear ⁽¹⁰⁾	0x00000000	0x0001FFFF	128 KB
SDRAM window	Always visible	0x00100000	0xBFFFFFFF	3071 MB (3 GB – 1 MB)
HPS-to-FPGA	Always visible	0xC0000000	0xFBFFFFFF	960 MB (1 GB – 64 MB)
System trace macrocell	Always visible	0xFC000000	0xFFEFFFFFFF	48 KB
<i>continued...</i>				

⁽¹⁰⁾ For details about the `noc_addr_remap_value` register, refer to "Memory Map Remap Bits".

Description	Condition	Base Address	End Address	Size
Debug access port	Always visible	0xFF000000	0xFF1FFFFFFF	2 MB
Lightweight HPS-to-FPGA	Always visible	0xFF200000	0xFF3FFFFFFF	2 MB
Peripherals	Always visible	0xFF800000	0xFFDFFFFFFF	6 MB
On-chip RAM	Always visible	0xFFE00000	0xFFFE3FFF	256 KB
Boot ROM	Always visible	0xFFFC0000	0xFFFDFFFF	128 KB
SCU and L2 registers	Always visible	0xFFFFC000	0xFFFFFFF	16 KB

Boot Region

The boot region is 1 MB, based at address 0x0. The boot region is visible to the MPU only when the L2 address filter start register is set to 0x100000. The L3 `noc_addr_remap_value` control register determines if the boot region is mapped to the on-chip RAM or the boot ROM.

The boot region is mapped to the boot ROM on reset. Only the lowest 128 KB of the boot region are legal addresses because the boot ROM is only 128 KB.

When the L2 address filter start register is set to 0, SDRAM obscures access to the boot region. This technique can be used to gain access to the lowest SDRAM addresses after booting completes.

SDRAM Window Region

The SDRAM window region provides access to a large, configurable portion of the 4 GB SDRAM address space. The address filtering start and end registers in the L2 cache controller define the SDRAM window boundaries.

The boundaries are megabyte-aligned. Addresses within the boundaries route to the SDRAM master, while addresses outside the boundaries route to the system interconnect master.

Addresses in the SDRAM window match addresses in the SDRAM address space. Thus, the lowest 1 MB of the SDRAM is not visible to the MPU unless the L2 address filter start register is set to 0.

HPS-to-FPGA Slaves Region

The HPS-to-FPGA slaves region provides access to slaves in the FPGA fabric through the HPS-to-FPGA bridge. Software can move the top of the SDRAM window by writing to the L2 address filter end register. If higher addresses are made available in the SDRAM window, part of the FPGA slaves region might be inaccessible to the MPU.

Lightweight HPS-to-FPGA Slaves Region

The lightweight FPGA slaves provide access to slaves in the FPGA fabric through the lightweight HPS-to-FPGA bridge.

Peripherals Region

The peripherals region is near the top of the address space. The peripherals region includes slaves connected to the L3 interconnect and L4 buses.

On-Chip RAM Region

The on-chip RAM is always mapped near the top of the address space, independent of the boot region contents.

Boot ROM Region

The boot ROM is always mapped near the top of the address space, independent of the boot region contents.

SCU and L2 Registers Region

The SCU and L2 registers region provides access to internally-decoded MPU registers (SCU and L2).

8.2.1.4. SDRAM Address Space

The SDRAM address space is up to 4 GB. The entire address space can be accessed through the FPGA-to-SDRAM interface from the FPGA fabric. The total amount of SDRAM addressable from the other address spaces varies.

There are cacheable and non-cacheable views into the SDRAM space. When a master of the performs a cacheable access to the SDRAM, the transaction is performed through the ACP port of the MPU subsystem. When a master of the performs a non-cacheable access to the SDRAM, the transaction is performed through the 32-bit master of the .

8.2.1.5. Address Remapping

The system interconnect supports address remapping through the `noc_addr_remap_value`, `noc_addr_remap_set`, and `noc_addr_remap_clear` registers in the system manager. Remapping allows software to control which memory device (on-chip RAM or boot ROM) is accessible at address 0x0. The remap registers can be modified by the MPU and the FPGA-to-HPS bridge.

The following master interfaces are affected by the remap bits:

- MPU master interface
 - L2 cache master 0 interface
- Non-MPU master interfaces
 - DMA master interface
 - Master peripheral interfaces
 - Debug Access Port (DAP) master interface
 - FPGA-to-HPS bridge master interface

Related Information

- [Cortex-A9 Microprocessor Unit Subsystem](#) on page 1022
For general information about the MPU subsystem, refer to the *Cortex-A9 Microprocessor Unit Subsystem* chapter.
- [System Manager](#) on page 244
For more information about setting registers in the system manager, refer to the *System Manager* chapter.

8.2.1.5.1. Memory Map Remap Bits

Table 72. Remap Bit Usage

remap0	remap1	0x00000000 (MPU Master Interface)	0x00000000 (Non-MPU Master Interfaces)	0xFFE00000 (All Maps)	0xFFFC0000 (MPU & DAP)
0	0	Boot ROM	SDRAM	On-Chip RAM	Boot ROM
0	1	Invalid setting			
1	0	SDRAM	SDRAM	On-Chip RAM	Boot ROM
1	1	On-Chip RAM	On-Chip RAM	On-Chip RAM	Boot ROM

L2 filter registers in the MPU subsystem, not the interconnect, allow the SDRAM to be remapped to address 0x0 for the MPU.

8.2.2. Secure Transaction Protection

The system interconnect provides two levels of secure transaction protection:

- Security firewalls—Enforce secure read and write transactions.
- Privilege filter—Leverages the firewall mechanism and provides additional security by filtering the privilege level of L4 slave transactions. The privilege filter applies to writes only.

All slaves on the SoC are placed behind a security firewall. A subset of slaves are also placed behind a privilege filter. Transactions to these slaves must pass both a security firewall and the privilege filter to reach the slave.

8.2.3.1. Master Caching and Buffering Overrides

Some of the peripheral masters connected to the do not have the ability to drive the caching and buffering signals of their interfaces. The system manager provides registers so that you can enable cacheable and bufferable transactions for these masters. The system manager drives the caching and buffering signals of the following masters:

Master Peripheral	System Manager Registers
EMAC0, EMAC1, and EMAC2	emac0, emac1, and emac2
USB OTG 0 and USB OTG 1	usb0_l3master and usb1_l3master
NAND flash	nand_l3master
SD/MMC	sdmmc_l3master

At reset time, the system manager drives the cache and buffering signals for these masters low. In other words, the masters listed do not support cacheable or bufferable accesses until you enable them after reset. There is no synchronization between the system manager and the , so avoid changing these settings when any of the masters are active.

Related Information

[System Manager](#) on page 244

For more information about enabling or disabling this feature, refer to the *System Manager* chapter.

8.2.6. System Interconnect Resets

The system interconnect has one reset signal, l3_rst_n. The reset manager drives this signal to the system interconnect on a cold or warm reset.

Related Information

[Reset Manager](#) on page 138

8.2.7. Functional Description of the Rate Adapters

Rate adapters are used at points in the system interconnect where there are bandwidth discontinuities, to ensure efficient use of interconnect data pathways. They are placed where a low-bandwidth source feeds a high-bandwidth destination. For this reason, they are sometimes positioned at the response side (where the Master is faster) and sometimes at the request side (where the Slave is faster).

The following table shows the rate adapters.

Table 77. Rate Adapter Modules

Rate Adapter Module Name	Data Path
noc_mpu_m0_MPU_M1toDDRResp_main_RateAdapter	Data packets from the SDRAM L3 interconnect in response to the MPU
noc_mpu_m0_MPU_M0_rate_adResp_main_RateAdapter	Data packets from the L3 interconnect in response to the MPU

8.2.8. Functional Description of the Firewalls

8.2.8.1. Security

8.2.8.1.1. Slave Security

The system interconnect enforces security through the slave settings. The slave settings are controlled by the NoC Security Control Register (SCR) in the service network. Each L3 and L4 slave has its own security check and programmable security settings. After reset, every slave of the system interconnect is set to a secure state (referred to as boot secure). Only secure masters are allowed to access secure slaves.

The NoC implements five firewalls to check the security state of each slave, as listed in the following table. At reset time, all firewalls default to the secure state.

Table 78. NoC Firewalls

Name	Function
On-Chip RAM Firewall	Filter access to on-chip RAM
Peripherals Firewall	Filter access to slave peripherals (SPs) in the following buses:
<i>continued...</i>	

Name	Function
	<ul style="list-style-type: none">• L4 main bus• L4 master peripherals bus• L4 AHB bus• L4 slave peripherals bus
System Firewall	Filter access to system peripherals in the following components: <ul style="list-style-type: none">• L4 system bus• L4 ECC bus• DAP
HPS-to-FPGA Firewall	Filter access to FPGA through the following bridges: <ul style="list-style-type: none">• HPS-to-FPGA bridge• Lightweight HPS-to-FPGA bridge
DDR and DDR L3 Firewalls	Filter access to DDR SDRAM

At reset, the privilege filters are configured to allow certain L4 slaves to receive only secure transactions. Software must either configure bridges secure at startup, or reconfigure the privilege filters to accept nonsecure transactions. You can reconfigure the privilege filters through the `l4_priv` register in the `noc_l4_priv_l4_priv_filter` module.

To change the security state, you must perform a secure write to the appropriate SCR register of a secure slave. A nonsecure access to the SCR register of a secure slave triggers a response with random data.

Note: Future devices might not support the return of random data and might only support an error response for blocked firewall transactions. For designs that may be ported to future devices, Intel recommends you to set the `error_response` bit in the `global` register of the `noc_fw_ddr_l3_ddr_scr` module.

Related Information

[l4_priv](#) on page 461

Privilege bits, used to enable or disable nonsecure access to individual L4 slaves

8.2.8.1.2. Master Security

Masters of the system interconnect are either secure, nonsecure, or the security is set on a per transaction basis. L2 cache masters 0 and 1, the FPGA-to-HPS bridge, DMA, the Ethernet MACs, and the DAP perform secure and nonsecure accesses on a per-transaction basis. All other system interconnect masters perform nonsecure accesses.

Accesses to secure slaves by unsecure masters result in a response with random data.

Note: Future devices might not support the return of random data and might only support an error response for blocked firewall transactions. For designs that may be ported to future devices, Intel recommends you to set the `error_response` bit in the `global` register of the `noc_fw_ddr_l3_ddr_scr` module.

Related Information

[System Interconnect Master Properties](#) on page 384

8.2.9. Functional Description of the SDRAM L3 Interconnect

The SDRAM L3 interconnect consists of two main blocks, serving the following two main functions:

- The SDRAM scheduler provides multi-port scheduling between the SDRAM L3 interconnect masters and the hard memory controller in the FPGA portion of the SoC. The SDRAM L3 interconnect is mastered by the MPU, the main L3 interconnect, and FPGA-to-SDRAM ports.
- The SDRAM adapter provides connectivity between the SDRAM L3 interconnect masters and the hard memory controller.

The SDRAM L3 interconnect also includes firewalls that can protect regions of SDRAM from unauthorized access.

The hard memory controller is physically located in the FPGA portion of the device, and therefore it is in a separate power domain from the HPS. The HPS cannot use the SDRAM L3 interconnect until the FPGA portion is powered up.

8.2.9.1. Functional Description of the SDRAM Scheduler

The SDRAM scheduler functions as a multi-port front end (MPFE), scheduling transactions from multiple masters to the SDRAM.

The SDRAM scheduler manages transactions to the memory access regions in the SDRAM. These memory regions are defined by the SDRAM L3 firewalls. The second-stage bootloader is expected to program the scheduler with the correct timings to implement optimal access patterns to the hard memory controller.

The SDRAM scheduler has the following features:

- Five input connections
 - One 64-bit connection from the MPU
 - One 64-bit connection from the main L3 interconnect
 - Two 128/64/32-bit connections from the FPGA
 - One 64/32-bit connection from the FPGA
- Single 256-bit connection to the SDRAM L3 adapter
 - Capable of issuing transactions at the memory device line rate
 - Traffic is comprised of aggregate inputs

Related Information

[SDRAM L3 Firewalls](#) on page 394

8.2.9.1.1. Monitors for Mutual Exclusion

The SDRAM scheduler implements support for mutually-exclusive (mutex) accesses on all ports to the SDRAM L3 interconnect.

The process for a mutually-exclusive access is as follows:

1. A master attempts to lock a memory location by performing an exclusive read from that address.
2. The master attempts to complete the exclusive operation by performing an exclusive write to the same address location.
3. The exclusive write access is signaled as:
 - Failed if another master has written to that location between the read and write accesses. In this case the address location is not updated.
 - Successful otherwise.

To support mutually-exclusive accesses from the MPU, the memory must be configured in the MMU page tables as normal memory, shareable, or non-cacheable.

Related Information

- [On-Chip Memory](#) on page 1421
- [Embedded Peripheral IP User Guide](#)
Contains detailed information about the mutex core

Exclusive Access Support

To ensure mutually exclusive access to shared data, use the exclusive access support built into the SDRAM scheduler. The AXI buses that interface to the scheduler provide `ARLOCK[0]` and `AWLOCK[0]`, signals which are used by the scheduler to arbitrate for exclusive access to a memory location. The SDRAM scheduler contains six monitors. Each monitor can be used by any of the following exclusive-capable masters:

- CPU 0
- CPU 1
- FPGA-to-HPS bridge
- FPGA-to-SDRAM0 port
- FPGA-to-SDRAM1 port
- FPGA-to-SDRAM2 port

Each master can lock only one memory location at a time.

8.2.9.1.2. Arbitration and Quality of Service in the SDRAM Scheduler

The SDRAM scheduler controls arbitration priorities internally for optimal end-to-end quality of service. You can apply QoS settings to each port of the SDRAM scheduler to control the bandwidth available to each master.

Each master on the SDRAM scheduler has software-programmable QoS signals. These signals are propagated to the scheduler and used as arbitration criteria for access to SDRAM.

For information about programming quality of service for the FPGA-to-SDRAM masters, refer to "Functional Description of the QoS Generators" and "Configuring the Quality of Service Logic".

Related Information

- [Functional Description of the QoS Generators](#) on page 396

- [Configuring the Quality of Service Logic](#) on page 405

8.2.9.2. Functional Description of the SDRAM Adapter

The SDRAM adapter connects the SDRAM scheduler with the Hard Memory Controller.

The SDRAM adapter provides the following functionality:

- ECC generation, detection, and correction
- Operates at memory half rate
 - Matches interface frequency of the single port memory controller in the FPGA
 - Connectivity to the MPU, main L3 interconnect, and FPGA undergo clock crossing

8.2.9.2.1. ECC

The SDRAM Adapter ECC can detect and correct single-bit errors and detect double-bit errors.

The addresses are merged with data and are used for checking. This configuration detects if correct write data is written to an incorrect location in memory; and if correct data is read from an incorrect location in memory.

Note: Data and address errors are detected independently.

ECC Write Behavior

When data is written to SDRAM, the SDRAM controller generates an ECC based on the write data and the write address.

If the write transaction is a partial write (less than 64 bits wide), the SDRAM adapter implements it as a read-modify-write (RMW) sequence, as follows:

- Reads existing data from the specified address
- Combine the write data with the existing data
- Generates the ECC based on the combined data and the write address
- Writes the combined data back to the write address

ECC Read Behavior

When data is read from SDRAM, the SDRAM controller checks the ECC to determine if the data or address is incorrect. It handles the following cases:

- If the SDRAM controller finds a single-bit data error, it corrects in the data returned to the master. You can also enable the SDRAM adapter to write the corrected data back to memory.
- If the SDRAM controller finds a double-bit data error, the SDRAM L3 interconnect issues an interrupt. Double-bit errors cannot be corrected.
- If the SDRAM controller finds an error in the address, indicating an address bit upset between the adapter and the HMC, the SDRAM L3 interconnect hardware issues a bus error.

8.2.9.2.2. SDRAM Adapter Interrupt Support

The SDRAM adapter supports the following three interrupts:

- The status interrupt occurs when:
 - Calibration is complete.
 - The ECC is unable to schedule an auto-correction write-back to memory. This occurs only when the auto-write-back FIFO is full.
- The ECC read-back interrupt occurs when an ECC single-bit error is detected in the read data. When this happens, the return data is corrected and returned to the NoC.
- The double-bit or fatal error interrupt occurs when any of the following three errors happens:
 - A double-bit error in the read data has been detected, which cannot be corrected.
 - A single-bit error has been detected in the address field. This means that the data that the adapter is returning has no bit errors, but is not the requested data. When this happens, the adapter returns a data error along with the data.
 - Any of the DDR4 devices have triggered their ALERT pins.
 - Address or command parity check has failed
 - Write data CRC check has failed
 - Cannot gracefully recover because SDRAMs are not providing feedback on failure case

8.2.9.2.3. SDRAM Adapter Clocks

All the logic in the SDRAM adapter is synchronous and effectively running off a single clock, `hmc_free_clk`, which is provided by the hard memory controller.

8.2.9.3. SDRAM L3 Firewalls

All data that is routed to the SDRAM scheduler must pass through the firewalls.

The SDRAM L3 firewalls define memory access regions in the SDRAM. Each SDRAM L3 interconnect master has its own memory access regions, independent of the other masters. The firewalls define whether each memory access region is protected or unprotected relative to its master. The number of available memory access regions for each master is shown in the following table.

Table 79. Memory Access Regions for SDRAM Masters

SDRAM L3 Interconnect Master	Number of Memory Access Regions
MPU	4
Main L3 interconnect (including the FPGA-to-HPS bridge)	8
FPGA-to-SDRAM port 0	4
FPGA-to-SDRAM port 1	4
FPGA-to-SDRAM port 2	4

The SDRAM L3 interconnect regulates access to the hard memory controller with the firewalls, which support secure regions in the SDRAM address space. Accesses to the SDRAM pass through the firewalls and then through the scheduler.

Related Information

[SoC Security](#) on page 332

8.2.9.4. SDRAM L3 Interconnect Resets

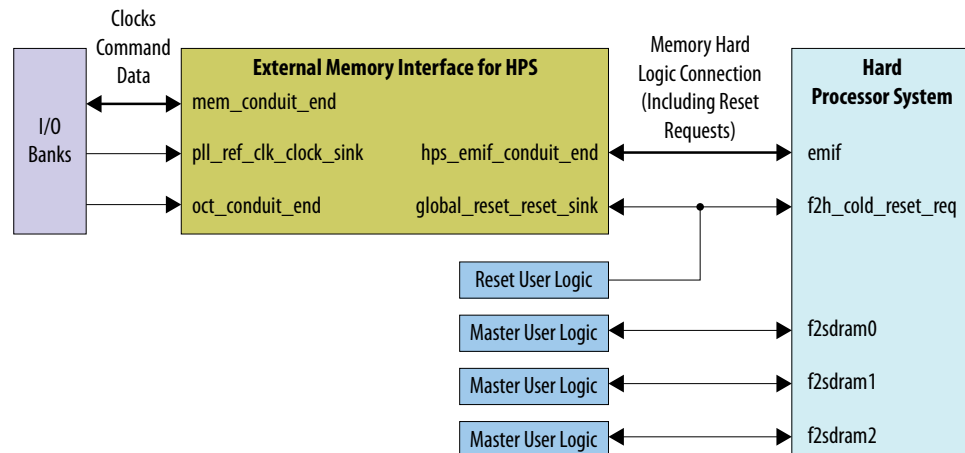

The reset signal `l3_rst_n` resets the system interconnect and the SDRAM L3 interconnect, but not the hard memory controller.

The reset signal in the hard memory controller is automatically connected to the SDRAM L3 interconnect when you instantiate the HPS component. For information about resetting the hard memory controller, refer to the *External Memory Interfaces in Arria 10 Devices* chapter of the *Arria 10 Core Fabric and General Purpose I/O Handbook*.

Soft logic in the FPGA must support the `global_reset_n` signal correctly. Refer to the *Instantiating the HPS Component* chapter for information about `global_reset_n`.

To optionally preserve the contents of the SDRAM on reset, refer to "Reset Handshaking" in the *Reset Manager* chapter.

Figure 37. Recommended SDRAM Reset Connections

Note: It is important to connect the reset user logic directly to both the HPS and the hard memory controller. If the hard memory controller is reset while the HPS is still running, the HPS is unable to access any external SDRAM memory.

Refer to the *External Memory Interfaces in Arria 10 Devices* chapter for information about resetting the hard memory controller.

8.2.10. Functional Description of the Arbitration Logic

The interconnect arbitration logic handles situations in which multiple simultaneous packets need the same interconnect resource.

The system interconnect contains arbitration nodes at each point where multiple packets might demand the same resource. Each arriving packet has a priority. When multiple packets of different priorities arrive simultaneously at a node, the arbitration logic grants the resource to the highest-priority packet.

If there are simultaneous packets with the same priority, the uses a simple round-robin (least recently used) algorithm to select the packet.

Each packet's priority is determined by urgency, pressure, and hurry, as described in "QoS Mechanisms".

Related Information

[QoS Mechanisms](#) on page 397

8.2.11. Functional Description of the QoS Generators

Quality of service is managed by information generated by a QoS generator at each initiator interface (master). The QoS generators work with the arbitration logic so you can tune the interconnect's performance to your system needs.

At the entry points to the system interconnect, the QoS generators create the following information to control how the arbitration logic allocates interconnect bandwidth among all transactions:

- Urgency—Each master has an urgency value. When it initiates a packet, it assigns a priority equal to its urgency.
- Pressure—Each data path has a pressure value. If the pressure is raised, packets on that path are treated as if their priority was also raised.
- Hurry—Each master has a hurry value. If the hurry is raised, all packets from that master are treated as if their priority was also raised.

The QoS information is used at each interconnect arbitration node to assign a packet priority. When there is contention for a resource, the arbitration logic generally gives the resource to the packets with higher priority.

For detailed descriptions of urgency, pressure, and hurry, refer to "QoS Mechanisms".

The values of urgency, pressure, and hurry are determined by each QoS generator's operating mode. QoS generators support the following modes:

- Limiter
- Regulator
- Fixed

For detailed descriptions of the QoS generator modes, refer to "QoS Generator Modes".

Related Information

- [Arbitration and Quality of Service in the SDRAM Scheduler](#) on page 392
- [QoS Generator Modes](#) on page 399
- [QoS Mechanisms](#) on page 397

8.2.11.1. QoS Generators in the Interconnect Architecture

The principal masters into the system interconnect are equipped with QoS generators.

The following table shows the interconnect initiators (masters) that support QoS generation.

Table 80. QoS Generators on Interconnect Masters

Master Name(s)	Default QoS Generator Mode	Clock
MPU Subsystem L2 cache M0/1	Limiter	mpu_l2ram_clk
FPGA-to-HPS Bridge	Limiter	fpga2hps_clk
FPGA-to-SDRAM Ports	Regulator	f2h_sdram_clk
DMA	Limiter	l4_main_clk
EMAC 0/1/2	Regulator	l4_mp_clk
USB OTG 0/1	Regulator	l4_mp_clk
NAND	Regulator	l4_mp_clk
SD/MMC	Regulator	l4_mp_clk

Related Information

[QoS Generator Modes](#) on page 399

8.2.11.2. QoS Mechanisms

The QoS generators influence arbitration priorities by manipulating urgency, pressure, and hurry.

When two or more packets compete for an interconnect resource at an arbitration node, the arbitration logic selects the packet with the highest priority. QoS generators can control the behavior of the arbitration logic by modifying the priority of packets through urgency, pressure, and hurry.

The QoS controls for each master are separated into read and write QoS controls.

Related Information

[Functional Description of the Arbitration Logic](#) on page 396

8.2.11.2.1. Packet Urgency

An urgency value is attached to each packet as long as it is moving through the interconnect. Urgency is the primary QoS mechanism.

A QoS generator assigns an urgency level to each packet when the packet data arrives at an interconnect master port.

8.2.11.2.2. Pressure Propagation

Each active datapath in the interconnect has a pressure level, which is the highest urgency of all packets currently in the datapath. Pressure can change depending on the traffic through the datapath.

The pressure is based on the urgency of packets waiting for that datapath. If a higher-priority packet requests a datapath that is already active, the datapath's urgency increases.

When a packet arrives at an arbitration node, normally its priority is the urgency assigned by its master. However, if the datapath's pressure is greater than the urgency, that pressure tells the node that there is a higher-urgency packet somewhere behind the current one. This prompts the node to expedite the lower-urgency packet to free up the datapath.

For example, consider three active packets in the interconnect. Packets A and B are moving through the same datapath, with A ahead of B. Packet C is on a different datapath.

Packet A's urgency value is 1, and packet B's urgency is 3. Packet A arrives at a particular node simultaneously with Packet C—and Packet C's urgency is 2. Without the pressure mechanism, Packet C would pass through the node first, ahead of Packet B, even though Packet B has the highest urgency of the three packets.

However, because Packet B's urgency is 3, its datapath has a pressure of 3. That pressure value tells the node to accept the packet on that datapath—Packet A—even though it has a lower urgency. After Packet A is out of the way, the node can accept Packet B ahead of Packet C.

8.2.11.2.3. Hurry

Each QoS generator has a hurry level, which can change depending on the bandwidth usage and the QoS generator mode.

Hurry is a mechanism to propagate the master's urgency level to all nodes that receive packets from that master. Hurry allows the master to influence the priority not only of the current transaction, but also of all its transactions that are still active.

When the hurry level is increased at a master, it has the effect of setting the urgency of that master's transactions to at least the same level as the hurry. As a result, the targets respond to the transactions more quickly.

For example, consider a master whose QoS generator is configured in regulator mode. This QoS generator dynamically raises and lowers its urgency value depending on the traffic it experiences. Packets sent from the master use the QoS generator's current urgency value. If the QoS generator raises its urgency value, it uses the Hurry mechanism to increase the pressure value at every datapath where it has a pending transaction.

The QoS generator implements hurry by broadcasting an urgency packet on every datapath where it has pending transactions. The urgency packet contains the current urgency value, which raises pressure on each datapath.

Related Information

[Regulator Mode](#) on page 399

8.2.11.3. QoS Generator Modes

Each QoS generator can operate in any of the following modes:

- **Limiter**—Each initiator has a maximum bandwidth cap to prevent it from sending too many requests. When the cap is reached, the initiator stops accepting new requests.
- **Regulator**—Each initiator has an ideal minimum bandwidth threshold. When the initiator's bandwidth usage drops below threshold, it raises the urgency for new transactions. Any pending transactions from that initiator are also expedited by the hurry mechanism.
- **Fixed**—Each initiator assigns static urgency values to packets. The urgency value for read packets can be different from the value for write packets.

QoS generators can also be set to bypass mode. In this case, QoS signals are provided by the component connected to the master interface.

For the default QoS generator mode for each initiator, refer to "QoS Generators in the Interconnect Architecture".

Related Information

- [QoS Generators in the Interconnect Architecture](#) on page 397
Default QoS modes for each initiator
- [Hurry](#) on page 398

8.2.11.3.1. Limiter Mode

In limiter mode, transactions from the initiator are limited to a specific bandwidth.

The QoS generator controls the initiator's access to the interconnect, by monitoring the amount of data transmitted and received in a sliding time window.

The purpose of limiter mode is to place a hard bound on the initiator's throughput. This avoids flooding the interconnect with transactions from that initiator. When a programmable bandwidth threshold is exceeded, the initiator is stalled, and stops accepting new requests. As the time window moves forward, the total bandwidth usage in the window falls, and the initiator resumes accepting requests.

In limiter mode, the QoS generator combines read and write requests to determine the bandwidth usage.

Related Information

[Programming QoS Limiter Mode](#) on page 405

8.2.11.3.2. Regulator Mode

In regulator mode, the QoS generator maintains bandwidth usage to transaction targets at a programmed level, by adjusting urgency, pressure, and hurry.

Use this mode to guarantee a specific bandwidth is available to the master, while preventing it from claiming more bandwidth than you requested.

When the initiator's bandwidth usage exceeds the specified threshold, the QoS downgrades the urgency, pressure, and hurry levels. When bandwidth usage is too low, the QoS increases urgency, pressure and hurry. Software can program the desired bandwidth threshold, the saturation, and maximum and minimum levels for urgency, pressure, and hurry.

Regulator mode controls bandwidth usage more smoothly than limiter mode. This mode is useful in achieving real-time performance.

Related Information

[Programming QoS Regulator Mode](#) on page 406

8.2.11.3.3. Fixed Mode

In fixed mode, the QoS generator assigns a fixed urgency to each packet. Software can configure separate urgencies for read and write transactions.

This mode is useful for coarse-grain control in a system where one master should have the first access to interconnect resources. However, this mode can have significant system level performance degradation due to other masters being starved.

Related Information

[Programming QoS Fixed Mode](#) on page 407

8.2.12. Functional Description of the Observation Network

8.2.12.1. Probes

The system interconnect includes the probes shown in the following table.

Table 81. Observation Probes

Probe Name	Probe ID	Probe Type	Probe Target(s)	Packet Tracing and Statistics	Transaction Profiling	Error Logging
MPU	6	Packet	MPU master 0	•		
SOC2FPGA	5	Packet	<ul style="list-style-type: none">HPS-to-FPGA bridgeLightweight HPS-to-FPGA bridge	•		
DDR	10	Packet	SDRAM adapter	•		
EMAC	4	Packet	EMAC0		•	
EMAC	4	Packet	<ul style="list-style-type: none">EMAC1EMAC2	•		
ERROR	n/a	Error	<ul style="list-style-type: none">HPS-to-FPGA bridgeLightweight HPS-to-FPGA bridge			•

The probe ID is available on the ATB trace bus.

8.2.12.2. Packet Tracing, Profiling, and Statistics

Packet probes perform packet tracing, profiling and statistics. The following table shows how each packet probe is configured. All statistics counters are 16 bits wide, and all probes can generate level alarms from the statistics counter. All probes use the CoreSight cross-trigger protocol.

Table 82. Packet Probe Characteristics

Probe Name	Purpose	Number of Filters	Statistics Counters Can Count Enabled Bytes	Packet Payloads Included in Trace Data	Number of Statistics Counters
MPU	MPU	1	No	No	4
SOC2FPGA	HPS-to-FPGA bridge	2	No	No	4
EMAC	Ethernet MAC	2	No	No	4
DDR	SDRAM	4	Yes	Yes	2

8.2.12.2.1. Packet Filtering

You can set up filters to control how the observation network handles traced packets.

Filters can perform the following tasks:

- Select which packets the observation network routes to CoreSight
- Trigger a trace alarm when a packet meets specified criteria

8.2.12.2.2. Statistics Collection

To collect packet statistics, you specify packet criteria and set up counters for packets that meet those criteria. You can set up the observation network to trigger an alarm when a counter reaches a specified level.

8.2.12.2.3. Transaction Profiling

A transaction probe is available on Ethernet MAC 0. You can use the transaction probe to measure either the transaction latency or the number of pending packets on EMAC0. Data are collected as a histogram.

The EMAC0 transaction probe is configured as shown in the following table.

Table 83. EMAC0 Transaction Probe Configuration

Number of simultaneously tracked transactions	4
Width of counters	10 bits
Available delay thresholds	64, 128, 256, 512
Available pending transaction count thresholds	2, 4, 8
Number of comparators	3
Number of histogram bins	4

Profiling Transaction Latency

In latency mode (also called delay mode), one of the four delay threshold values can be chosen for each comparator. The threshold values represent the number of clock cycles that a transaction takes from the time the request is issued to the time the response is returned.

Profiling Pending Transactions

In pending transaction mode, one of the three available transaction count threshold values can be chosen for each comparator. The threshold values represent the number of requests pending on EMAC0.

8.2.12.3. Packet Alarms

Packet alarms can be used to trigger software interrupts.

The following types of alarms are available:

- Trace alarms—You can examine trace alarms through the system interconnect registers.
- Statistics alarms

8.2.12.4. Error Logging

The error probe logs errors on initiators, targets, and firewalls.

8.3. Configuring the System Interconnect

Related Information

[SoC Security](#) on page 332

8.3.1. Configuring the Rate Adapters

The default settings for the rate adapters are as shown in the following table.

Table 84. Rate Register Default Settings

Rate Register Name	Default
MPU_M1toDDRResp_main_RateAdapter_Rate	0x0
MPU_M0_rate_adResp_main_RateAdapter_Rate	0x0
L4_MP_rate_ad_main_RateAdapter_Rate	0x100
fpga2soc_rate_ad_main_RateAdapter_Rate	0x0
L3Tosoc2fpgaResp_main_RateAdapter_Rate	0x0
acp_rate_ad_main_RateAdapter_Rate	0x0

8.3.2. Configuring the SDRAM Scheduler

8.3.2.1. FPGA Port Configuration

The FPGA has three outputs that pass through the firewall before connecting to the SDRAM scheduler.

You can configure the FPGA-to-SDRAM (F2SDRAM) ports to data widths of 32, 64, or 128 bits:

- F2SDRAM 0 - 32-, 64-, or 128-bit data widths
- F2SDRAM 1 - 32- or 64-bit data widths
- F2SDRAM 2 - 32-, 64-, or 128-bit data widths

There are four port configurations that are a combination of the SDRAM ports 0 - 2 that you are able to select. Once a port configuration is selected, you can choose to disable ports that you do not need.

Note: The total data width of all interfaces is limited to a maximum of 256 bits in the read direction and 256 bits in the write direction.

Port Configuration	F2SDRAM 0	F2SDRAM 1	F2SDRAM 2
1	32-bit	32-bit	32-bit
2	64-bit	64-bit	64-bit
3	128-bit	unused	128-bit
4	128-bit	32-bit	64-bit

8.3.2.2. Memory Timing Configuration

The SDRAM L3 interconnect provides fully-programmable timing parameter support for all JEDEC-specified timing parameters.

The following lists the handoff information used to control the SDRAM scheduler:

- The scheduler is aware of the SDRAM timing so that it can guide traffic into the hard memory controller.
- This information is not used to control the subsystem that sets up memory timings in the hard memory controller hardware.

8.3.2.3. Configuring SDRAM Burst Sizes

You can optimize memory throughput by adjusting the SDRAM burst lengths for read and write transactions. The best burst length values are application-dependent. Intel recommends that you follow guidelines in *Arria 10 SoC Device Design Guidelines* to determine the optimal burst lengths.

Related Information

8.3.3.1. SDRAM Adapter Memory Mapped Registers

8.3.3.2. Sharing I/Os between the EMIF and the FPGA

Each bank has four I/O lanes that correspond to:

- Lane 3: IO[47:36]
- Lane 2: IO[35:24]
- Lane 1: IO[23:12]
- Lane 0: IO[11:0]

The diagram shows the internal architecture of the FPGA fabric and its connection to external I/O blocks. The central FPGA Fabric is divided into two main regions: HPS (High Performance System) and HPS Shared I/O. Bank 2I (left) connects to the HPS region, while Bank 2K (right) connects to the HPS Shared I/O region. The diagram illustrates the flow of data from the FPGA Fabric through the HPS/HPS Shared I/O regions to the external I/O blocks.

Bank 2I: Lanes 3, 2, 1, 0 Data[63:32]. Lane 3 ECC. Lanes 0-3 connect to the FPGA Fabric.

Bank 2K: Lanes 2, 1, 0 Address and Command. Lane 3 ECC. Lanes 0-3 connect to the FPGA Fabric.

FPGA Fabric: HPS, HPS Shared I/O, HPS Dedicated I/O, FPGA I/O.

Bank 2J: Lanes 3, 2, 1, 0 Data[31:16] Data[15:0]. Lanes 0-3 connect to the FPGA Fabric.

Intel® Arria 10® Hard Processor System Technical Reference Manual
404

I/Os in these three banks can be shared between the HPS EMIF and FPGA. Quartus Prime software enforces the following guidelines on shared I/Os:

- Modular I/O banks 2K, 2J and 2I can be used entirely as FPGA GPIO when there is no HPS EMIF in the system.
- Bank 2K:
 - If there is an HPS EMIF in the system, lane 3 is used for ECC for the SDRAM. Unused pins in lane 3 may be used as FPGA inputs only.
 - Lanes 2, 1, and 0 are used for address and command for the SDRAM. Unused pins in these lanes may be used as FPGA inputs or outputs.
- Bank 2J:
 - If there is an HPS EMIF in the system, bank 2J is used for data bits [31:0].
 - With 16-bit data widths, unused pins in the two lanes of bank 2J used for data can be used as inputs only. The pins in the remaining two lanes can be used as FPGA inputs or outputs.
 - With 32-bit data widths, unused pins bank 2J can be used as FPGA inputs only.
- Bank 2I:
 - If there is an HPS EMIF in the system, bank 2I is used for data bits [63:32].
 - With 64-bit data widths, unused pins in bank 2I can be used as FPGA inputs only.
 - With 32- or 16-bit data widths, bank 2I can be used as FPGA inputs or outputs.

8.3.4. Configuring the Quality of Service Logic

You can programmatically configure the QoS generator for each master through the QoS registers.

Note: Before accessing the registers for any QoS generator, you must ensure that the corresponding peripheral is not in reset. Otherwise, the register access results in a bus error, causing a CPU fault.

8.3.4.1. Programming QoS Limiter Mode

QoS bandwidth limiter mode is mode 1. To put the QoS generator in limiter mode, set the registers as shown in the following table.

Table 85. QoS Generator Register Values for Limiter Mode

Register	Field	Value
I_main_QosGenerator_Mode	MODE	1
I_main_QosGenerator_Priority	P0	Urgency for write transactions
<i>continued...</i>		

Register	Field	Value
I_main_QoSGenerator_Priority	P1	Urgency for read transactions
I_main_QoSGenerator_Bandwidth	BANDWIDTH	Maximum bandwidth, in units of (bytes/cycle)/256
I_main_QoSGenerator_Saturation	SATURATION	Measurement window for bandwidth, in units of bytes/16. This register specifies the maximum number of bytes that the initiator can transmit or receive at full speed before the limiter triggers.

Higher priority (urgency) values mean that a packet receives preferential treatment at each arbitration node.

For detailed information about setting bandwidth and saturation, refer to "Bandwidth and Saturation".

When you switch QoS modes, the bandwidth counter is reset.

Related Information

8.3.4.2. Programming QoS Regulator Mode

QoS bandwidth regulator mode is mode 3. To put the QoS generator in regulator mode, set the registers as shown in the following table.

Table 86. QoS Generator Register Values for Regulator Mode

Register	Field	Value
I_main_QoSGenerator_Mode	MODE	3
I_main_QoSGenerator_Priority	P0	Packet urgency when the actual throughput exceeds the threshold set in I_main_QoSGenerator_Bandwidth.
I_main_QoSGenerator_Priority	P1	Packet urgency when the actual throughput is less than the threshold set in I_main_QoSGenerator_Bandwidth. P0 must be less than or equal to P1.
I_main_QoSGenerator_Bandwidth	BANDWIDTH	Desired throughput, in units of (bytes/cycle)/256
I_main_QoSGenerator_Saturation	SATURATION	Measurement window for bandwidth, in units of bytes/16.

Higher priority (urgency) values mean that a packet receives preferential treatment at each arbitration node.

For detailed information about setting bandwidth and saturation, refer to "Bandwidth and Saturation".

When you switch QoS modes, the bandwidth counter is reset.

8.3.4.3. Programming QoS Fixed Mode

Fixed mode is mode 0. To put the QoS generator in fixed mode, set the registers as shown in the following table.

Table 87. QoS Generator Register Values for Fixed Mode

Register	Field	Value
I_main_QoSGenerator_Mode	MODE	0
I_main_QoSGenerator_Priority	P0	Urgency for write transactions (default=0)
I_main_QoSGenerator_Priority	P1	Urgency for read transactions (default=1)

Higher priority (urgency) values mean that a packet receives preferential treatment at each arbitration node.

Related Information

[QoS Generator Registers](#) on page 408
List of QoS registers

8.3.4.4. Bandwidth and Saturation

Encoding Bandwidth Values

The QoS bandwidth setting is frequency-dependent. Low-frequency masters require a larger value to achieve the same bandwidth as higher frequency masters.

You can calculate the register value for a bandwidth as follows:

$$*I_main_QoSGenerator_Bandwidth = (\text{bandwidth} / \text{frequency}) * 256$$

where bandwidth is in MBps and frequency is in MHz.

For example, to configure the FPGA-to-SDRAM 0 QoS generator for a bandwidth of 1000 MBps at 200 MHz, calculate the register value as follows:

$$\text{fpga2sdram0_axi128_I_main_QoSGenerator_Bandwidth} = (1000 / 200) * 256 = 1280.$$

Encoding Saturation Values

The QoS saturation represents the period of time that the master bandwidth is evaluated. The saturation value represents units of 16 bytes of data transferred. For example a 64-bit master that should have the bandwidth re-evaluated every 100 clock cycles would use a saturation setting of $100 \text{ cycles} * 8 \text{ bytes} / 16 \text{ bytes} = 50$

The saturation register controls the number of bytes that the initiator can transmit at full speed before the limiter or regulator takes effect. The register encodes the byte count as a multiple of 16 bytes. Therefore you can calculate the register value as follows:

$$*I_main_QoSGenerator_Saturation = nbytes / 16$$

For example, to let the MPU initiator send 64 bytes at full speed, calculate the register value as follows:

$$mpu_m1_I_main_QoSGenerator_Saturation = 64 / 16 = 4$$

Related Information

[QoS Generator Registers](#) on page 408

[List of QoS registers](#)

8.3.4.5. QoS Generator Registers

There is a register set for each QoS generator.

Each QoS generator's register set includes the register types shown in the following table.

Table 88. QoS Generator Register Types

Name	Purpose
I_main_QoSGenerator_Priority	Specifies master urgencies. Register usage depends on the QoS generator mode.
I_main_QoSGenerator_Mode	Specifies the QoS generator mode (limiter, regulator, fixed, or bypass).
I_main_QoSGenerator_Bandwidth	Specifies the bandwidth threshold for limiter and regulator modes.
I_main_QoSGenerator_Saturation	Specifies the bandwidth measurement time window for limiter and regulator modes. ⁽¹⁷⁾

The actual register names consist of the register type plus a prefix specific to the QoS generator. For example, the registers for MPU subsystem L2 cache master 0 are:

- mpu_m0_I_main_QoSGenerator_Priority
- mpu_m0_I_main_QoSGenerator_Mode
- mpu_m0_I_main_QoSGenerator_Bandwidth
- mpu_m0_I_main_QoSGenerator_Saturation
- mpu_m0_I_main_QoSGenerator_ExtControl

The following table lists the prefixes for all QoS generators.

(17) For detailed information about setting bandwidth and saturation, refer to "Bandwidth and Saturation".

Table 89. QoS Register Name Prefixes

Initiator	Register Name Prefix
MPU Subsystem L2 Cache Master 0	mpu_m0_
MPU Subsystem L2 Cache Master 1	mpu_m1_
FPGA-to-HPS Bridge	fpga2soc_axi32_
FPGA-to-HPS Bridge	fpga2soc_axi64_
FPGA-to-HPS Bridge	fpga2soc_axi128_
DMA Controller	dma_m0_
Ethernet MAC 0	emac0_m_
Ethernet MAC 1	emac1_m_
Ethernet MAC 2	emac2_m_
USB-2 OTG 0	usb0_m_
USB-2 OTG 1	usb1_m_
NAND Flash Controller	nand_m_
SD/MMC Controller	sdmmc_m_
FPGA-to-SDRAM Port 0	fpga2sdram0_axi32_
FPGA-to-SDRAM Port 0	fpga2sdram0_axi64_
FPGA-to-SDRAM Port 0	fpga2sdram0_axi128_
FPGA-to-SDRAM Port 1	fpga2sdram1_axi32_
FPGA-to-SDRAM Port 1	fpga2sdram1_axi64_
FPGA-to-SDRAM Port 2	fpga2sdram2_axi32_
FPGA-to-SDRAM Port 2	fpga2sdram2_axi64_
FPGA-to-SDRAM Port 2	fpga2sdram2_axi128_

Related Information

[Bandwidth and Saturation](#) on page 407

8.3.4.6. QoS Programming Examples

8.3.4.6.1. Example: One Master Always Takes Precedence

In this example, one particular master's packets always take precedence.

Consider a system that includes three masters, A, B, and C. In this system, we require that master A always takes precedence over master B at each arbitration node, and master B always takes precedence over master C. To implement this arbitration scheme, we configure all QoS generators in fixed mode, and assign appropriate values for read and write urgency, as shown in the following table:

Table 90. Fixed Example Settings

Master	QoS Mode	P1 (Read Urgency)	P0 (Write Urgency)
A	Fixed (mode 0)	0x3	0x3
B	Fixed (mode 0)	0x2	0x2
C	Fixed (mode 0)	0x1	0x1

In fixed mode, masters by default have a read urgency of 1 and write urgency of 0. So master C has equal urgency for reads and higher urgency for writes compared to all the other masters in the system.

8.3.4.6.2. Example: Tuning for Specific Throughput Requirements

In this example, we require each master to meet specific throughput requirements.

Consider a system in which masters A, B, and C have the following throughput requirements:

- Master A: 1000 MBps operating at 100 MHz
- Master B: 800 MBps operating at 800 MHz
- Master C: 500 MBps operating at 400 Mhz

We achieve this by using the QoS generators in regulator mode. There are other masters in the system, and these three masters may need to "steal" bandwidth from them to achieve the required throughputs. Therefore, all the other QoS generators are configured in limiter mode to cap their bandwidth usage.

To set up the QoS generators for masters A, B, and C, we can use the settings in the following table.

Table 91. Regulator Example Settings

Master	QoS Mode	QoS Bandwidth	QoS Saturation (register value) ⁽¹⁸⁾
A	Regulator	2560	64 bytes (saturation = 4)
B	Regulator	256	256 bytes (saturation = 16)
C	Regulator	320	128 bytes (saturation = 8)

Not shown are the master urgencies. When a QoS regulator achieves the required bandwidth the urgency is downgraded to allow other masters to achieve their required bandwidth.

⁽¹⁸⁾ The QoS bandwidth register value is computed as (desired bandwidth (MBps) * 256) / master frequency (MHz)

We also set the urgency threshold values, P1 and P0. P1 is the urgency when a master falls below the bandwidth threshold. P0 is the urgency when a master is above the bandwidth threshold. regulator mode ensures a minimum bandwidth to the master, by raising the urgency when the bandwidth falls below the threshold, and downgrading it when the bandwidth is back above the threshold.

For any master the value of P1 must be greater or equal than P0.

8.4. System Interconnect Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the [Arria 10 HPS Address Map and Register Definitions](#).

8.4.1. ecc_hmc_ocp_slv_block Address Map

Module Instance	Base Address	End Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFDFFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

8.4.1.2. IP_REV_ID

IDO Register

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB000

Offset: 0x0

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SIREV 0x0															

IP_REV_ID Fields

Bit	Name	Description	Access	Reset
15:0	SIREV	IP Rev #These bits indicate the silicon revision number	RO	0x0

8.4.1.3. DDRIOCTRL

DDR IO Control Register

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														IO_SIZE 0x0	

DDRIOCTRL Fields

Bit	Name	Description	Access	Reset
1:0	IO_SIZE	External Configuration of DDR IO size. This field indicates the width of the external DDR to which the hard memory cotnroller is interfacing. These bits are configured at the start to indicate the	RW	0x0

Bit	Name	Description	Access	Reset
		external DDRIO size. 0x0 = DDR IO x16. default value after reset 0x1 = DDR IO x32 0x2 = DDR IO x64		

8.4.1.4. DDRCALSTAT

DDR Calibration Register

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB00C

Offset: 0xC

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CAL 0x0

DDRCALSTAT Fields

Bit	Name	Description	Access	Reset
0	CAL	DDR calibration status. This field indicates the calibration status of the hard memory controller's I/O column. During this time the DDR memory is not available. 0x0: When clear, calibration is either on going, hasn't started or failed. 0x1: When set to 1, calibration has succeeded.	RO	0x0

8.4.1.5. MPR_0BEAT1

Multipurpose register [31:0] for first beat

8.4.1.23. AUTO_PRECHARGE

Auto-precharge register

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB060

Offset: 0x60

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														CTRL 0x0	

AUTO_PRECHARGE Fields

Bit	Name	Description	Access	Reset
0	CTRL	Control bit to drive auto-precharge bit on command interface to the hard memory controller. 1'b0: Default value after reset. Auto-precharge request to the hard memory controller is disabled 1'b1: Every read/write command sent to the hard memory controller has the auto-precharge bit enabled	RW	0x0

8.4.1.24. ECCCTRL1

ECC control 1.
This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB100

Offset: 0x100

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															AUTOWB_CNT_RST 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CNT_RST 0x0	Reserved							ECC_EN 0x0

ECCCTRL1 Fields

Bit	Name	Description	Access	Reset
16	AUTOWB_CNT_RST	Reset the auto-write back internal counter to zero. The auto-write back counter is reset to zero when the INTONCMP bit in the INTMODE register is set. 1'b0 : No effect on auto-write back internal counter. Default value after reset 1'b1 : Reset the auto-write back internal counter to zero	RW	0x0
8	CNT_RST	Reset of internal counter. The internal counter is reset to zero when the INTONCMP bit in the INTMODE register is set. 1'b0: No effect on internal counter. Default value after reset 1'b1: Reset the internal counter to zero	RW	0x0
0	ECC_EN	Enable for the ECC detection and correction logic. This bit is used to detect and correct any errors within RAM during memory access. 1'b0:ECC block is disabled. Default value after reset. 1'b1: ECC block is enabled. Every RAM access will verify the data and generate any necessary error requests.	RW	0x0

8.4.1.25. ECCCTRL2

ECC control 2.
This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB104

Offset: 0x104

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															OVRW_RB_ECC_EN 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							RMW_EN 0x0	Reserved							AUTOWB_EN 0x0

ECCCTRL2 Fields

Bit	Name	Description	Access	Reset
16	OVRW_RB_ECC_EN	Overwrite the read-back ecc code during RMW process if a double byte error is detected. 1'b0: write the read-back ECC from RMW process if derr is detected. Default value after reset. 1'b1: write of 1 will overwrite the ECC overwrite feature.	RW	0x0
8	RMW_EN	Enable read modify write logic. When ECC is enabled and sub word accesses require correct ECC to be calculated, this bit should be enabled. RMW_EN bit should be disabled when ECC_EN is disabled. 1'b0: disable RMW logic. Default value after reset. 1'b1: enable RMW logic.	RW	0x0
0	AUTOWB_EN	Enable auto write back correction feature. When a single-bit error is detected on outgoing reads, the hard memory controller adaptor schedules the corrected data and ECC to the written to the DDR memory. This bit enables auto correction of DDR memory. 1'b0: disable auto WB drop correction. Default value after reset. 1'b1: enable auto WB drop correction.	RW	0x0

8.4.1.26. ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB110

Offset: 0x110

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													HMI_I NTREN	DERRI NTEN	SERRI NTEN
													0x0	0x0	0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
2	HMI_INTREN	Enables GP HMI interrupt. This bit is used to enable the general purpose HMI interrupt error interrupt to system manager. When this bit is enabled along with autoWB_drop_en, it compares the internal counter with autoWB_drop_cntreg value. If the value is greater than or equal to, then the interrupt will be asserted.. 1'b0: hmi interrupt generation logic is disabled. 1'b1: hmi interrupt generation logic is enabled.	RW	0x0
1	DERRINTEN	This bit is used to enable the double bit error interrupt to system manager. When dbe error occurs, bus error is always generated with the transaction.DERR interrupt (derr_req) will be generated when this bit is enabled. 1'b0: DBE interrupt generation logic is disabled. 1'b1: DBE interrupt generation logic is enabled,	RW	0x0
0	SERRINTEN	This bit is used to enable the single bit error to system manager. It enables the interrupt modes (sbe request, compare match) 1'b0: SBE interrupt generation logic is disabled. 1'b1: SBE interrupt generation logic is enabled,	RW	0x0

8.4.1.27. ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB114

Offset: 0x114

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													HMI_I NTRS 0x0	DERRI NTS 0x0	SERRI NTS 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
2	HMI_INTRS	This bit is used to set the general purposes HMI interrupt error. 1'b0: writing of zero has no effect 1'b1: writing one, HMI_INTREN bit to 1. This is performing a bitwise writing of this feature.	RW	0x0
1	DERRINTS	This bit is used to set the double-bit error interrupt bit. Reads reflect DERRINTEN. 1'b0: writing of zero has no effect 1'b1: writing one, DERRINTEN bit to 1. This is performing a bitwise writing of this feature.	RW	0x0
0	SERRINTS	This bit is used to set the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: writing of zero has no effect 1'b1: writing one, this bit will set SERRINTEN bit to 1. This is performing a bitwise writing of this feature.	RW	0x0

8.4.1.28. ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB118

Offset: 0x118

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													HMI_I NTRR 0x0	DERRI NTR 0x0	SERRI NTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
2	HMI_INTRR	This bit is used to reset the general purpose HMI interrupt error interrupt to system manager 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset HMI_INTREN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0
1	DERRINTR	This bit is used to reset the double-bit error interrupt bit. Reads reflect DERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset DERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

8.4.1.29. INTMODE

Interrupt mode

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB11C

Offset: 0x11C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							AFICAL_EN 0x0	Reserved							INTONCMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							EXT_ADDRPARITY_EN 0x0	Reserved							INTMODE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
24	AFICAL_EN	Enable interrupt of memory interface calibration success. This bit is used to enable interrupt of memory interrupt calibration success. The hmi_intr signal will be asserted on a match. 1'b0: HMI interrupts on compare match is disabled. 1'b1: HMI interrupts on compare matched is enabled.	RW	0x0
16	INTONCMP	Enable interrupt on compare match. This bit is used to enable interrupt when the internal counter and SERRCNTA value matches. serr_req signal will be asserted on a match. 1'b0: SERR interrupt on compare match is disabled 1'b1: SERR interrupt on compare match is enabled	RW	0x0
8	EXT_ADDRPARITY_EN	Enable address parity for DDR4 memories. This bit is used to enable the interrupt that generate externally when address parity is detected. when enabled, this will be generating derr_req signal 1'b0: disable address parity on DERR interrupt 1'b1: enable address parity on DERR interrupt	RW	0x0
0	INTMODE	Interrupt mode for single-bit error. This is disabled when SERRINTEN is disabled in the ERRINTEN register. 1'b0: interrupt disabled 1'b1: generate interrupt on every SERR	RW	0x0

8.4.1.30. INTSTAT

Interrupt status

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB120

Offset: 0x120

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved													HMI_P ENA 0x0	DERRP ENA 0x0	SERRP ENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
18	DERRBUSFLG	This bit is used to indicate that the last transaction was flagged with double-bit error. 1'b0: no effect. 1'b1: indicates double-bit error has occurred. This will drive the bus to respond the read with bus error. Write of one will clear this register double-bit bus error. Bus error occurs as part of the transaction but this indicates the SW the cause of the error. This should only occur once per transaction	RW	0x0
17	ADDRPARFLG	External address parity flag for DDR4 memory. This bit is used to flag external address parity flag which is driven with derr_req port. 1'b0: No Effect. 1'b1: Read of one indicates double-bit interrupt has occurred. Write of one will clear this register last address parity flag.	RW	0x0
16	ADDRMTCFLG	Address mismatch error flag. This bit is used to indicate the last transaction was flagged with address mismatch error. 1'b0: No effect. 1'b1: indicates address mismatch error has occurred. This will drive the bus to respond the read with bus error. Write of one will clear this register address mismatch error. Bus error occurs as part of the transaction but this indicates the SW the cause of the error. This should occur once per transaction.	RW	0x0
2	HMI_PENA	HMI interrupt pending This bit is used to clear the pending hmi interrupt bit. 1'b0: No effect	RW	0x0
continued...				

Bit	Name	Description	Access	Reset
		1'b1: indicates hmi interrupt is pending. Write of one will clear the pending interrupt. This will de-assert the hmi_intr signal.		
1	DERRPENA	Double bit error pending This bit is used to clear the pending double-bit error. 1'b0: No effect. 1'b1: indicates DBE is pending. Write of one will clear the pending DBE. This will de-assert the derr_req signal.	RW	0x0
0	SERPENA	Single-bit error pending This bit is used to clear the pending single-bit error. 1'b0: No effect. 1'b1: indicates SBE is pending. Write of one will clear the pending. This will de-assert the serr_req signal.	RW	0x0

8.4.1.31. DIAGINTTEST

Enable diagnostic errors

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB124

Offset: 0x124

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							TADDR PAR 0x0	Reserved							TADDR MTC 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERR A 0x0	Reserved							TSERR A 0x0

DIAGINTTEST Fields

Bit	Name	Description	Access	Reset
24	TADDRPAR	Diagnostic of address parity of DDR4. This bit is used to test the address parity error path. 1'b0: Disables generating address match bus error as part of the transaction. 1'b1: When this bit is set to 1, derr_req signal is generated to the system manager. By writing to this bit,	RW	0x0

continued...

Bit	Name	Description	Access	Reset
		ADDRPARFLG bit in the INTSTAT register will be pending. Write of one to ADDRPARFLG will clear this bit. SW needs to explicitly write to DERRPENA to clear it.		
16	TADDRMTC	Diagnostic enable of Address mismatch error. This bit is used to flag that the last transaction was flagged with address mismatch error. 1'b0: Disables generating address match bus error as part of the transaction. 1'b1: When this bit is set to 1, derr_req signal is generated to the system manager without going through the ECC decoder address mismatch logic. By writing to this bit, ADDRMTCLG bit in the INTSTAT register will be pending. Write of one to ADDRMTCLG will clear this bit. SW needs to explicitly write to DERRPENA to clear it.	RW	0x0
8	TDERRA	Diagnostic enable of Double-bit error. This bit is used to test double-bit error. 1'b0: Write of zero has no effect. 1'b1: When this bit is set to 1, derr_req signal is generated to the system manager without going through the ECC decoder logic. By writing to this bit, DERRBUSFLG bit in the INTSTAT register will be pending. Write of one to DERRBUSFLG will clear this bit. SW needs to explicitly write to DERRPENA to clear it.	RW	0x0
0	TSERRA	This bit is used to test a single-bit error. 1'b0: Write of zero has no effect. 1'b1: When this bit is set to 1, serr_req signal is generated to the system manager without going through the ECC decoder logic. By writing to this bit, SERRPENA bit in the INTSTAT register will be pending. Write of one to SERRPENA will clear this bit.	RW	0x0

8.4.1.32. MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB128

Offset: 0x128

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							AUTOW B_DRO P_FLG 0x0	Reserved							CMPFL GA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
8	AUTOWB_DROP_FLG	Auto writeback counter match flag. This bit indicates that the internal autoWB counter and autoWB_drop_cnt value matched. 1'b0: read indicates match check of hmi_intr interrupt on compare match is disabled. 1'b1: read indicates compare has matched. Write of one will clear the pending compare match. This will not deassert the hmi_intr signal - software needs to write to hmi_intrpen bit to clear the interrupt. When the match occurs, additional errors will not increment count until the compare status flag is cleared. If the software does not change the autoWB_drop_cnt register prior to clearing this flag or reset the autoWB counter, next increment of internal autoWB counter could set this flag in the next cycle.	RW	0x0
0	CMPFLGA	Counter Match occurred flag. This bit indicates that the internal counter and SERRCNT value matched. 1'b0: read indicates match check of SERR interrupt on compare match is disabled. 1'b1: read indicates compare has matched. Write of one will clear the pending compare match. This will not deassert the serr_req signal - software needs to write to serrpen bit to clear the interrupt. When the match occurs, additional errors will not increment count until the compare status flag is cleared. If the software does not change the SERRCNT register prior to clearing this flag or reset the internal counter, next increment of internal counter could set this flag again in the next cycle.	RW	0x0

8.4.1.33. DERRADDRA

Double-bit error address

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB12C

Offset: 0x12C

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DADDRESS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DADDRESS 0x0															

DERRADDRA Fields

Bit	Name	Description	Access	Reset
31:0	DADDRESS	Last double-bit error address at 256-bit boundary. This register shows the address of the current double-bit error. RAM size will determine the maximum number of address bits. This address is logged when a new derr_req or bus error is generated to the system. This is gated by the ecc_en enable bit and derrinten bit.	RO	0x0

8.4.1.34. SERRADDRA

Single-bit error address

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB130

Offset: 0x130

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SADDRESS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SADDRESS 0x0															

SERRADDRA Fields

Bit	Name	Description	Access	Reset
31:0	SADDRESS	Last single-bit error address at 256-bit boundary. This register shows the address of the current single-bit error. This address is logged when a new serr_req is generated to the system. This is gated by the single-bit error interrupt enable and ecc_en.	RO	0x0

8.4.1.35. AUTOWB_CORRADDR

This register shows the address of the current autoWB correction SBE.

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB138

Offset: 0x138

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWBADDRESS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWBADDRESS 0x0															

AUTOWB_CORRADDR Fields

Bit	Name	Description	Access	Reset
31:0	SWBADDRESS	recent autoWB correction address. This register shows the address of the current autoWB correction single-bit error. This address is logged when a new serr_req is generated to the system. This is gated by the single-bit error interrupt enable and ecc_en. Note that when a single-bit error occurs, an address is logged regardless of whether auto-correction is enabled or not. If you have not enabled auto-correction, this register can be ignored.	RO	0x0

8.4.1.36. SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB13C

Offset: 0x13C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Compare value for the internal single-bit errors. This register sets the value to compare with the internal counter. Software should write to this register before enabling the interrupt on compare. 0x0: If the serrcnt bits are not modified before enabling the intoncmp, internal counter=0 and serrcnt=0, serr compare interrupt will not occur. Default after reset. Nonzero: if internal counter == serrcnt == nonzero will create a serr compare interrupt. When the compare matches, autoWB_drop_cmpflga will be set.	RW	0x0

8.4.1.37. AUTOWB_DROP_CNTREG

Maximum counter value for AUTOWB correction interrupt

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB140

Offset: 0x140

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CNT 0x1															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT 0x1															

AUTOWB_DROP_CNTREG Fields

Bit	Name	Description	Access	Reset
31:0	CNT	Compare value for the internal autoWB correction count. This register sets the value to compare with the autoWB internal counter. Software should write to this register before enabling the interrupt on compare. 0x1: If the autoWB_drop_cntreg bits are not modified before enabling the hmi_intr, autoWB internal counter=0 and autoWB_drop_cnt =1, serr compare interrupt will not occur. Default after reset.	RW	0x1

Bit	Name	Description	Access	Reset
		Nonzero: if autoWB internal counter == autoWB_drop_cnt == nonzero will create a serr compare interrupt. When the compare matches, autoWB_drop_flg will be set.		

8.4.1.38. ECC_REG2WRECCDATABUS

ECC from register associated to data which will be written to the RAM

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB144

Offset: 0x144

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC1BUS 0x0								ECC0BUS 0x0							

ECC_REG2WRECCDATABUS Fields

Bit	Name	Description	Access	Reset
31:2 4	ECC3BUS	ECC from register associated to data [255:192] which will be written to the RAM	RW	0x0
23:1 6	ECC2BUS	ECC from register associated to data [191:128] which will be written to the RAM	RW	0x0
15:8	ECC1BUS	ECC from register associated to data [127:64] which will be written to the RAM	RW	0x0
7:0	ECC0BUS	ECC from register associated to data [63:0] which will be written to the RAM	RW	0x0

8.4.1.39. ECC_REG2RDECCDATABUS

ECC from register associated to RD data which will be written to hmc ecc

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB14C

Offset: 0x14C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC3BUS 0x0								ECC2BUS 0x0							
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC1BUS 0x0								ECC0BUS 0x0							

ECC_REG2RDECCDATABUS Fields

Bit	Name	Description	Access	Reset
31:2 4	ECC3BUS	ECC from register associated to RD data [255:192] which will be written to hmc ecc. Based on the DDR IO width, unimplemented bytes of this register will read as zero.	RW	0x0
23:1 6	ECC2BUS	ECC from register associated to RD data [191:128] which will be written to hmc ecc. Based on the DDR IO width, unimplemented bytes of this register will read as zero.	RW	0x0
15:8	ECC1BUS	ECC from register associated to RD data [127:64] which will be written to hmc ecc. Based on the DDR IO width, unimplemented bytes of this register will read as zero.	RW	0x0
7:0	ECC0BUS	ECC from register associated to RD data [63:0] which will be written to hmc ecc. Based on the DDR IO width, unimplemented bytes of this register will read as zero.	RW	0x0

8.4.1.40. ECC_DIAGON

Enable diagnostics access

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB150

Offset: 0x150

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															ECCDI AGON 0x0

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						RATE RW 0x0									

MPU_M1toDDRResp_main_RateAdapter_Rate Fields

Bit	Name	Description	Access	Reset
9:0	RATE	The ratio of outgoing to incoming throughput. This value determines what portion of a received packet will be stored before its head is transmitted. An optimal setting avoids transmitting bubbles, while adding no delay to packets. The ratio is expressed as $256 / (\text{ratio} - 1)$. The value for rate must be rounded up except when ratio is greater than 4, in which case it must be rounded down. For example, a 4:1 ratio of outgoing to incoming throughput would be indicated by value 0x055. Note that throughput is the product of clock frequency x data bus width. A value of 0x000 causes the rate adapter to store a packet until either the entire packet is received or the buffer becomes full.	RW	0x0

8.4.3.5. MPU_M1toDDRResp_main_RateAdapter_Bypass

Module Instance	Base Address	Register Address
i_noc_mpu_m0_MPU_M1toDDRResp_main_RateAdapter	0xFFD11100	0xFFD1110C

Reserved						RATE RW 0x100									

L4_MP_rate_ad_main_RateAdapter_Rate Fields

Bit	Name	Description	Access	Reset
9:0	RATE	The ratio of outgoing to incoming throughput. This value determines what portion of a received packet will be stored before its head is transmitted. An optimal setting avoids transmitting bubbles, while adding no delay to packets. The ratio is expressed as $256 / (\text{ratio} - 1)$. The value for rate must be rounded up except when ratio is greater than 4, in which case it must be rounded down. For example, a 4:1 ratio of outgoing to incoming throughput would be indicated by value 0x055. Note that throughput is the product of clock frequency x data bus width. A value of 0x000 causes the rate adapter to store a packet until either the entire packet is received or the buffer becomes full.	RW	0x100

8.4.5.5. L4_MP_rate_ad_main_RateAdapter_Bypass

Module Instance	Base Address	Register Address

8.4.9.4. ddr_T_main_Probe_MainCtl

Register MainCtl contains probe global control bits. The register has seven bit fields:

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Probe	0xFFD12000	0xFFD12008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								FILTB YTEAL WAYS CHAINA BLEEN RW 0x0	INTRU SIVEM ODE RW 0x0	STATC ONDDU MP RW 0x0	ALARM EN RW 0x0	STATE N RW 0x0	PAYLO ADEN RW 0x0	TRACE EN RW 0x0	ERREN RW 0x0

ddr_T_main_Probe_MainCtl Fields

Bit	Name	Description	Access	Reset
7	FILTB YTEAL WAYS CHAINA BLEEN	When set to 0, filters are mapped to all statistic counters when counting bytes or enabled bytes. Therefore, only filter events mapped to even counters can be counted using a pair of chained counters. When set to 1, filters are mapped only to even statistic counters when counting bytes or enabled bytes. Thus events from any filter can be counted using a pair of chained counters.	RW	0x0
6	INTRUSIVEMODE	When set to 1, register field IntrusiveMode enables trace operation in Intrusive flow-control mode. When set to 0, the register enables trace operation in Overflow flow-control mode	RW	0x0
5	STATCONDUMP	When set, register field StatCondDump enables the dump of a statistics frame to the range of counter values set for registers StatAlarmMin, StatAlarmMax, and AlarmMode. This field also renders register StatAlarmStatus inoperative. When parameter statisticsCounterAlarm is set to False, the StatCondDump register bit is reserved.	RW	0x0
continued...				

Bit	Name	Description	Access	Reset
4	ALARMEN	When set, register field AlarmEn enables the probe to collect alarm-related information. When the register field bit is null, both TraceAlarm and StatAlarm outputs are driven to 0.	RW	0x0
3	STATEN	When set to 1, register field StatEn enables statistics profiling. The probe sends statistics results to the output for signal ObsTx. All statistics counters are cleared when the StatEn bit goes from 0 to 1. When set to 0, counters are disabled.	RW	0x0
2	PAYLOADEN	Register field PayloadEn, when set to 1, enables traces to contain headers and payload. When set to 0, only headers are reported.	RW	0x0
1	TRACEEN	Register field TraceEn enables the probe to send filtered packets (Trace) on the ObsTx observation output.	RW	0x0
0	ERREN	Register field ErrEn enables the probe to send on the ObsTx output any packet with Error status, independently of filtering mechanisms, thus constituting a simple supplementary global filter.	RW	0x0

8.4.9.5. ddr_T_main_Probe_CfgCtl

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Probe	0xFFD12000	0xFFD1200C

Reserved											STATPERIOD RW 0x0				

ddr_T_main_Probe_StatPeriod Fields

Bit	Name	Description	Access	Reset
4:0	STATPERIOD	Register StatPeriod is a 5-bit register that sets a period, within a range of 2 cycles to 2 gigacycles, during which statistics are collected before being dumped automatically. Setting the register implicitly enables automatic mode operation for statistics collection. The period is calculated with the formula: $N_{Cycle} = 2 * StatPeriod$ When register StatPeriod is set to its default value 0, automatic dump mode is disabled, and register StatGo is activated for manual mode operation. Note: When parameter statisticsCollection is set to False, StatPeriod is reserved.	RW	0x0

8.4.9.11. ddr_T_main_Probe_StatGo

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Probe	0xFFD12000	0xFFD12028

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ddr_T_main_Probe_StatAlarmStatus Fields

Bit	Name	Description	Access	Reset
0	STATALARMSTATUS	Register StatAlarmStatus is a read-only 1-bit register indicating that at least one statistics counter has exceeded the programmed values for registers StatAlarmMin or StatAlarmMax. Output signal StatAlarm is equal to the values stored in register MainCtl fields StatAlarmStatus and AlarmEn. When parameter statisticsCounterAlarm is set to False, StatAlarmStatus is reserved.	RO	0x0

8.4.9.15. ddr_T_main_Probe_StatAlarmClr

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Probe	0xFFD12000	0xFFD12038

Offset: 0x38

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															STATA LARMC LR RW 0x0

ddr_T_main_Probe_StatAlarmClr Fields

Bit	Name	Description	Access	Reset
0	STATALARMCLR	Register StatAlarmClr is a 1-bit register. Writing a 1 to this register clears the StatAlarmStatus register bit. When parameter statisticsCounterAlarm is set to False, StatAlarmClr is reserved. NOTE The written value is not stored in StatAlarmClr. A read always returns 0.	RW	0x0

8.4.9.16. ddr_T_main_Probe_StatAlarmEn

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Probe	0xFFD12000	0xFFD1203C

Offset: 0x3C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

FILTERS_2_ADDRBASE_LOW RW 0x0															

ddr_T_main_Probe_Filters_2_AddrBase_Low Fields

Bit	Name	Description	Access	Reset
31:0	FILTERS_2_ADDRBASE_LOW	Address LSB register.	RW	0x0

8.4.9.40. ddr_T_main_Probe_Filters_2_WindowSize

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Probe	0xFFD12000	0xFFD120CC

Offset: 0xCC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										FILTERS_2_WINDOWSIZE RW 0x0					

ddr_T_main_Probe_Filters_2_WindowSize Fields

Bit	Name	Description	Access	Reset
5:0	FILTERS_2_WINDOWSIZE	Register WindowSize contains the encoded address mask used to filter packets. The effective Mask value is equal to $\sim(2^{\max(\text{WindowSize}, \text{packet.Len})} - 1)$. A packet is a candidate when $\text{packet.Addr} \& \text{Mask} = \text{AddrBase} \& \text{Mask}$. This allows filtering of packets having an intersection with the AddrBase/WindowSize burst aligned region, even if the region is smaller than the packet.	RW	0x0

8.4.9.41. ddr_T_main_Probe_Filters_2_SecurityBase

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Probe	0xFFD12000	0xFFD120D0

Offset: 0xD0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

Reserved													FILTERS_2_SECURITYMASK RW 0x0		

ddr_T_main_Probe_Filters_2_SecurityMask Fields

Bit	Name	Description	Access	Reset
2:0	FILTERS_2_SECURITYMASK	Register SecurityMask is contains the security mask used to filter packets. A packet is a candidate when: packet.Security & SecurityMask = SecurityBase & SecurityMasks.	RW	0x0

8.4.9.43. ddr_T_main_Probe_Filters_2_Opcode

Packet Probe register Opcode is a 4-bit register that selects candidate packets based on packet opcodes (0 disables the filter):

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Probe	0xFFD12000	0xFFD120D8

Offset: 0xD8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												URGEN RW 0x0	LOCKE N RW 0x0	WREN RW 0x0	RDEN RW 0x0

ddr_T_main_Probe_Filters_2_Opcode Fields

Bit	Name	Description	Access	Reset
3	URGEN	Selects URG packets (urgency).	RW	0x0
2	LOCKEN	Selects RDX-WR, RDL, WRC and Linked sequence.	RW	0x0
1	WREN	Selects WR packets.	RW	0x0
0	RDEN	Selects RD packets.	RW	0x0

8.4.9.44. ddr_T_main_Probe_Filters_2_Status

Register Status is 2-bit register that selects candidate packets based on packet status.

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Probe	0xFFD12000	0xFFD120DC

Offset: 0xDC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														RSPEN RW 0x0	REQEN RW 0x0

ddr_T_main_Probe_Filters_2_Status Fields

Bit	Name	Description	Access	Reset
1	RSPEN	Selects RSP and FAIL-CONT status packets.	RW	0x0
0	REQEN	Selects REQ status packets.	RW	0x0

8.4.9.45. ddr_T_main_Probe_Filters_2_Length

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Probe	0xFFD12000	0xFFD120E0

Offset: 0xE0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												FILTERS_2_LENGTH RW 0x0			

ddr_T_main_Probe_Filters_2_Length Fields

Bit	Name	Description	Access	Reset
3:0	FILTERS_2_LENGTH	Register Length is 4-bit register that selects candidate packets if their number of bytes is less than or equal to 2**Length.	RW	0x0

8.4.9.46. ddr_T_main_Probe_Filters_2_Urgency

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Probe	0xFFD12000	0xFFD120E4

Offset: 0xE4

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Name	Description	Access	Reset
4:0	DDRCONF	Selection of a configuration of mappings of address bits to memory device, bank, row, and column. For more information, refer to the SoC-specific DDR Conf documentation.	RW	0x0

8.4.10.5. ddr_T_main_Scheduler_DdrTiming

ddr timing definition.

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Scheduler	0xFFD12400	0xFFD1240C

Offset: 0xC

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BWRATIO IO RW 0x1	WRTORD RW 0xB					RDTOWR RW 0x1					BURSTLEN RW 0x2			WRTOMISS RW 0x21	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WRTOMISS RW 0x21					RDTOMISS RW 0x13					ACTTOACT RW 0x1C					

ddr_T_main_Scheduler_DdrTiming Fields

Bit	Name	Description	Access	Reset
31	BWRATIO	When set to zero, one DRAM clock cycle (two DDR transfers) is used to transfer each word of data. When set to one, two DRAM clock cycles (four DDR transfers) are used to transfer each word of data. This is applicable when half of a DRAM data bus width is used.	RW	0x1
30:2 6	WRTORD	The minimum number of scheduler clock cycles between the last DRAM Write command and a Read command ($WL \times tCkD + tWTR$). $tCkD$ is the DRAM clock period.	RW	0xB
25:2 1	RDTOWR	The minimum number of scheduler clock cycles between the last DRAM Read command and a Write command (DDR3: $(RL - WL + 2) \times tCkD$). $tCkD$ is the DRAM clock period.	RW	0x1
20:1 8	BURSTLEN	The DRAM burst duration on the DRAM data bus in scheduler clock cycles. Also equal to scheduler clock cycles between two DRAM commands ($BL / 2 \times tCkD$). $tCkD$ is the DRAM clock period.	RW	0x2
17:1 2	WRTOMISS	The minimum number of scheduler clock cycles between the last DRAM Write command and a new Read or Write command in another page of the same bank ($WL \times tCkD + tWR + tRP + tRCD$). $tCkD$ is the DRAM clock period.	RW	0x21
11:6	RDTOMISS	The minimum number of scheduler clock cycles between the last DRAM Read command and a new Read or Write command in another page of the same bank ($tRTP + tRP + tRCD - BL \times tCkD / 2$). $tCkD$ is the DRAM clock period.	RW	0x13
5:0	ACTTOACT	The minimum number of scheduler clock cycles between two consecutive DRAM Activate commands on the same bank ($tRC / tCkG$). $tCkG$ is the clock period of the SoC DRAM scheduler.	RW	0x1C

8.4.10.6. ddr_T_main_Scheduler_DdrMode

ddr mode definition.

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Scheduler	0xFFD12400	0xFFD12410

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													BWRATIOEXTENDED RW 0x0	AUTOPRECHARGE RW 0x0	

ddr_T_main_Scheduler_DdrMode Fields

Bit	Name	Description	Access	Reset
1	BWRATIOEXTENDED	When set to one, four DRAM clock cycles (8 DDR transfers) are used to transfer each word of data. When set to zero, the BwRatio field of the DdrTiming register must be set to zero.	RW	0x0
0	AUTOPRECHARGE	When set to one, pages are automatically closed after each access, when set to zero, pages are left opened until an access in a different page occurs.	RW	0x0

8.4.10.7. ddr_T_main_Scheduler_ReadLatency

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Scheduler	0xFFD12400	0xFFD12414

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								READLATENCY RW 0x13							

ddr_T_main_Scheduler_ReadLatency Fields

Bit	Name	Description	Access	Reset
7:0	READLATENCY	The DRAM type-specific number of cycles from a scheduler request to a protocol controller response. This is a fixed value depending on the type of DRAM memory. For more information, refer to the SoC-specific memory controller documentation.	RW	0x13

8.4.10.8. ddr_T_main_Scheduler_Activate

timing values concerning Activate commands, in Generic clock unit.

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Scheduler	0xFFD12400	0xFFD12438

Offset: 0x38

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

8.4.11.2. nand_register

Per-Master Security bit for nand register

Module Instance	Base Address	Register Address
noc_fw_l4_per_l4_per_scr	0xFFD13000	0xFFD13000

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							ahb_ap RW 0x0	Reserved							fpga2soc RW 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							dma RW 0x0	Reserved							mpu_m0 RW 0x0

nand_register Fields

Bit	Name	Description	Access	Reset
24	ahb_ap	Security bit configuration for transactions from ahb_ap to nand_register. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
16	fpga2soc	Security bit configuration for transactions from fpga2soc to nand_register. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
8	dma	Security bit configuration for transactions from dma to nand_register. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
0	mpu_m0	Security bit configuration for transactions from mpu_m0 to nand_register. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0

8.4.11.3. nand_data

Per-Master Security bit for nand_data

Module Instance	Base Address	Register Address
noc_fw_l4_per_l4_per_scr	0xFFD13000	0xFFD13004

Offset: 0x4

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							ahb_ap RW 0x0	Reserved							fpga2soc RW 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							dma RW 0x0	Reserved							mpu_m0 RW 0x0

nand_data Fields

Bit	Name	Description	Access	Reset
24	ahb_ap	Security bit configuration for transactions from ahb_ap to nand_data. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
16	fpga2soc	Security bit configuration for transactions from fpga2soc to nand_data. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
8	dma	Security bit configuration for transactions from dma to nand_data. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
0	mpu_m0	Security bit configuration for transactions from mpu_m0 to nand_data. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0

8.4.11.4. qspi_data

Per-Master Security bit for qspi_data

Module Instance	Base Address	Register Address
noc_fw_l4_per_l4_per_scr	0xFFD13000	0xFFD13008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

uart0 Fields

Bit	Name	Description	Access	Reset
24	ahb_ap	Security bit configuration for transactions from ahb_ap to uart0. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
16	fpga2soc	Security bit configuration for transactions from fpga2soc to uart0. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
8	dma	Security bit configuration for transactions from dma to uart0. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
0	mpu_m0	Security bit configuration for transactions from mpu_m0 to uart0. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0

8.4.11.30. uart1

Per-Master Security bit for uart1

Module Instance	Base Address	Register Address
noc_fw_l4_per_l4_per_scr	0xFFD13000	0xFFD13070

Offset: 0x70

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved							dma RW 0x0	Reserved							mpu_m0 RW 0x0

uart1 Fields

Bit	Name	Description	Access	Reset
24	ahb_ap	Security bit configuration for transactions from ahb_ap to uart1. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
16	fpga2soc	Security bit configuration for transactions from fpga2soc to uart1. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
8	dma	Security bit configuration for transactions from dma to uart1. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
0	mpu_m0	Security bit configuration for transactions from mpu_m0 to uart1. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0

8.4.12. noc_fw_l4_sys_l4_sys_scr Address Map

Module Instance	Base Address	End Address
noc_fw_l4_sys_l4_sys_scr	0xFFD13100	0xFFD131FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

8.4.12.2. dma_ecc

Per-Master Security bit for dma_ecc

Module Instance	Base Address	Register Address
noc_fw_l4_sys_l4_sys_scr	0xFFD13100	0xFFD13108

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							ahb_ap RW 0x0	Reserved							fpga2soc RW 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															mpu_m0 RW 0x0

dma_ecc Fields

Bit	Name	Description	Access	Reset
24	ahb_ap	Security bit configuration for transactions from ahb_ap to dma_ecc. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
16	fpga2soc	Security bit configuration for transactions from fpga2soc to dma_ecc. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
0	mpu_m0	Security bit configuration for transactions from mpu_m0 to dma_ecc. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0

8.4.12.3. emac0rx_ecc

Per-Master Security bit for emac0rx_ecc

Module Instance	Base Address	Register Address
noc_fw_l4_sys_l4_sys_scr	0xFFD13100	0xFFD1310C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

24	ahb_ap	Security bit configuration for transactions from ahb_ap to fpga_manager. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
8	dma	Security bit configuration for transactions from dma to fpga_manager. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
0	mpu_m0	Security bit configuration for transactions from mpu_m0 to fpga_manager. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0

8.4.12.21. pin_mux_register

Per-Master Security bit for pin_mux_register

Module Instance	Base Address	Register Address
noc_fw_l4_sys_l4_sys_scr	0xFFD13100	0xFFD13154

Offset: 0x54

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							ahb_ap RW 0x0	Reserved							fpga2soc RW 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							dma RW 0x0	Reserved							mpu_m0 RW 0x0

pin_mux_register Fields

Bit	Name	Description	Access	Reset
24	ahb_ap	Security bit configuration for transactions from ahb_ap to pin_mux_register. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
16	fpga2soc	Security bit configuration for transactions from fpga2soc to pin_mux_register. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
8	dma	Security bit configuration for transactions from dma to pin_mux_register. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
0	mpu_m0	Security bit configuration for transactions from mpu_m0 to pin_mux_register. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0

8.4.12.22. reset_manager

Per-Master Security bit for reset_manager

Module Instance	Base Address	Register Address
noc_fw_l4_sys_l4_sys_scr	0xFFD13100	0xFFD13158

Offset: 0x58

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							ahb_ap RW 0x0	Reserved							fpga2soc RW 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

8.4.15.13. global

Global Firewall Control Register. This register will store various overrides that change default firewall behavior on the entire interconnect.

Module Instance	Base Address	Register Address
noc_fw_ddr_l3_ddr_scr	0xFFD13400	0xFFD1342C

Offset: 0x2C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															error_response RW 0x0

global Fields

Bit	Name	Description	Access	Reset
0	error_response	<p>When 0, transactions blocked by the firewall will fail silently, returning random data and no error status. When 1, transactions blocked by the firewall will return an error.</p> <p>Note: Future devices might not support the return of random data and might only support an error response for blocked firewall transactions. For designs that might be ported to future devices, Intel recommends you to set the error_response bit.</p>	RW	0x0

8.4.16. noc_fw_soc2fpga_soc2fpga_scr Address Map

Module Instance	Base Address	End Address
noc_fw_soc2fpga_soc2fpga_scr	0xFFD13500	0xFFD13FFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Probe_SoC2FPGA_main_Probe_Id_RevisionId Fields

Bit	Name	Description	Access	Reset
31:8	FLEXNOCID	Field containing the build revision of the software used to generate the IP HDL code.	RO	0x129FF
7:0	USERID	Field containing a user defined value, not used anywhere inside the IP itself.	RO	0x0

8.4.17.4. Probe_SoC2FPGA_main_Probe_MainCtl

Register MainCtl contains probe global control bits. The register has seven bit fields:

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_SoC2FPGA_main_Probe	0xFFD14000	0xFFD14008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Probe_SoC2FPGA_main_Probe_MainCtl Fields

Bit	Name	Description	Access	Reset
7	FILTB YTEAL WAYSCH AINABL EEN	When set to 0, filters are mapped to all statistic counters when counting bytes or enabled bytes. Therefore, only filter events mapped to even counters can be counted using a pair of chained counters. When set to 1, filters are mapped only to even statistic counters when counting bytes or enabled bytes. Thus events from any filter can be counted using a pair of chained counters.	RW	0x0
6	INTRUSIVEMODE	When set to 1, register field IntrusiveMode enables trace operation in Intrusive flow-control mode. When set to 0, the register enables trace operation in Overflow flow-control mode	RO	0x0
5	STATCONDUMP	When set, register field StatCondDump enables the dump of a statistics frame to the range of counter values set for registers StatAlarmMin, StatAlarmMax, and AlarmMode. This field also renders register StatAlarmStatus inoperative. When parameter statisticsCounterAlarm is set to False, the StatCondDump register bit is reserved.	RW	0x0
continued...				

Bit	Name	Description	Access	Reset
4	ALARMEN	When set, register field AlarmEn enables the probe to collect alarm-related information. When the register field bit is null, both TraceAlarm and StatAlarm outputs are driven to 0.	RW	0x0
3	STATEN	When set to 1, register field StatEn enables statistics profiling. The probe sends statistics results to the output for signal ObsTx. All statistics counters are cleared when the StatEn bit goes from 0 to 1. When set to 0, counters are disabled.	RW	0x0
2	PAYLOADEN	Register field PayloadEn, when set to 1, enables traces to contain headers and payload. When set to 0, only headers are reported.	RW	0x0
1	TRACEEN	Register field TraceEn enables the probe to send filtered packets (Trace) on the ObsTx observation output.	RW	0x0
0	ERREN	Register field ErrEn enables the probe to send on the ObsTx output any packet with Error status, independently of filtering mechanisms, thus constituting a simple supplementary global filter.	RW	0x0

8.4.18.4. Probe_emacs_main_Probe_MainCtl

Register MainCtl contains probe global control bits. The register has seven bit fields:

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_Probe	0xFFD14400	0xFFD14408

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								FILTB YTEAL WAYSCH AINABLE EN RW 0x0	INTRU SIVEM ODE RO 0x0	STATC ONDDU MP RW 0x0	ALARM EN RW 0x0	STATEN RW 0x0	PAYLOAD EN RW 0x0	TRACE EN RW 0x0	ERREN RW 0x0

Probe_emacs_main_Probe_MainCtl Fields

Bit	Name	Description	Access	Reset
7	FILTBYTEALWAYSCHAINABLEEN	When set to 0, filters are mapped to all statistic counters when counting bytes or enabled bytes. Therefore, only filter events mapped to even counters can be counted using a pair of chained counters. When set to 1, filters are mapped only to even statistic counters when counting bytes or enabled bytes. Thus events from any filter can be counted using a pair of chained counters.	RW	0x0
6	INTRUSIVEMODE	When set to 1, register field IntrusiveMode enables trace operation in Intrusive flow-control mode. When set to 0, the register enables trace operation in Overflow flow-control mode	RO	0x0
5	STATCONDDUMP	When set, register field StatCondDump enables the dump of a statistics frame to the range of counter values set for registers StatAlarmMin, StatAlarmMax, and AlarmMode. This field also renders register StatAlarmStatus inoperative. When parameter statisticsCounterAlarm is set to False, the StatCondDump register bit is reserved.	RW	0x0
4	ALARMEN	When set, register field AlarmEn enables the probe to collect alarm-related information. When the register field bit is null, both TraceAlarm and StatAlarm outputs are driven to 0.	RW	0x0
3	STATEN	When set to 1, register field StatEn enables statistics profiling. The probe sends statistics results to the output for signal ObsTx. All statistics counters are cleared when the StatEn bit goes from 0 to 1. When set to 0, counters are disabled.	RW	0x0
2	PAYLOADEN	Register field PayloadEn, when set to 1, enables traces to contain headers and payload. When set to 0, only headers are reported.	RW	0x0
1	TRACEEN	Register field TraceEn enables the probe to send filtered packets (Trace) on the ObsTx observation output.	RW	0x0
0	ERREN	Register field ErrEn enables the probe to send on the ObsTx output any packet with Error status, independently of filtering mechanisms, thus constituting a simple supplementary global filter.	RW	0x0

8.4.18.5. Probe_emacs_main_Probe_CfgCtl

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_Probe	0xFFD14400	0xFFD1440C

Probe_emacs_main_Probe_StatAlarmMax Fields

Bit	Name	Description	Access	Reset
31:0	STATALARMMAX	Register StatAlarmMax contains the maximum count value used in statistics alarm comparisons. The number of bits is equal to twice the value set for parameter wStatisticsCounter. When parameter statisticsCounterAlarm is set to False, StatAlarmMax is reserved.	RW	0x0

8.4.18.15. Probe_emacs_main_Probe_StatAlarmStatus

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_Probe	0xFFD14400	0xFFD14434

Offset: 0x34

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														STATALARMS TATUS RO 0x0	

Probe_emacs_main_Probe_StatAlarmStatus Fields

Bit	Name	Description	Access	Reset
0	STATALARMSSTATUS	Register StatAlarmStatus is a read-only 1-bit register indicating that at least one statistics counter has exceeded the programmed values for registers StatAlarmMin or StatAlarmMax. Output signal StatAlarm is equal to the values stored in register MainCtl fields StatAlarmStatus and AlarmEn. When parameter statisticsCounterAlarm is set to False, StatAlarmStatus is reserved.	RO	0x0

8.4.18.16. Probe_emacs_main_Probe_StatAlarmClr

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_Probe	0xFFD14400	0xFFD14438

Offset: 0x38

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															STATALARMCLR RW 0x0

Probe_emacs_main_Probe_StatAlarmClr Fields

Bit	Name	Description	Access	Reset
0	STATALARMCLR	Register StatAlarmClr is a 1-bit register. Writing a 1 to this register clears the StatAlarmStatus register bit. When parameter statisticsCounterAlarm is set to False, StatAlarmClr is reserved. NOTE The written value is not stored in StatAlarmClr. A read always returns 0.	RW	0x0

8.4.18.17. Probe_emacs_main_Probe_StatAlarmEn

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_Probe	0xFFD14400	0xFFD1443C

Offset: 0x3C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														STATALARME N RW 0x1	

Probe_emacs_main_Probe_StatAlarmEn Fields

Bit	Name	Description	Access	Reset
0	STATALARME N	Register StatAlarmEn is a 1-bit register. When set to 0 it masks StatAlarm and CtiTrigOut(1) signal interrupts.	RW	0x1

8.4.18.18. Probe_emacs_main_Probe_Filters_0_RouteIdBase

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_Probe	0xFFD14400	0xFFD14444

Offset: 0x44

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

Probe_emacs_main_Probe_Filters_0_SecurityMask Fields

Bit	Name	Description	Access	Reset
2:0	FILTERS_0_SECURITYMASK	Register SecurityMask is contains the security mask used to filter packets. A packet is a candidate when: packet.Security & SecurityMask = SecurityBase & SecurityMasks.	RW	0x0

8.4.18.24. Probe_emacs_main_Probe_Filters_0_Opcode

Packet Probe register Opcode is a 4-bit register that selects candidate packets based on packet opcodes (0 disables the filter):

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_Probe	0xFFD14400	0xFFD14460

Offset: 0x60

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												URGEN RW 0x0	LOCKE N RW 0x0	WREN RW 0x0	RDEN RW 0x0

Probe_emacs_main_Probe_Filters_0_Opcode Fields

Bit	Name	Description	Access	Reset
3	URGEN	Selects URG packets (urgency).	RW	0x0
2	LOCKEN	Selects RDX-WR, RDL, WRC and Linked sequence.	RW	0x0
1	WREN	Selects WR packets.	RW	0x0
0	RDEN	Selects RD packets.	RW	0x0

8.4.18.25. Probe_emacs_main_Probe_Filters_0_Status

Register Status is 2-bit register that selects candidate packets based on packet status.

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_Probe	0xFFD14400	0xFFD14464

Offset: 0x64

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													RSPEN RW 0x0	REQEN RW 0x0	

Probe_emacs_main_Probe_Filters_0_Status Fields

Bit	Name	Description	Access	Reset
1	RSPEN	Selects RSP and FAIL-CONT status packets.	RW	0x0
0	REQEN	Selects REQ status packets.	RW	0x0

8.4.18.26. Probe_emacs_main_Probe_Filters_0_Length

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_Probe	0xFFD14400	0xFFD14468

Offset: 0x68

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved														OVERFLOWSTATUS RO 0x0	

Probe_emacs_main_TransactionStatProfiler_OverflowStatus Fields

Bit	Name	Description	Access	Reset
0	OVERFLOWSTATUS	Bit n of register OverflowStatus is set to 1 if a start event occurs on observed port n and either of the following conditions occurs: All tenure counters allocated to the port are already in use. No tenure lines have been allocated to the port. The number of bits in this register is equal to the value set for parameter nObservable.	RO	0x0

8.4.19.10. Probe_emacs_main_TransactionStatProfiler_OverflowReset

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_TransactionStatProfiler	0xFFD14800	0xFFD14870

Offset: 0x70

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															OVERFLOWRESET RW 0x0

Probe_emacs_main_TransactionStatProfiler_OverflowReset Fields

Bit	Name	Description	Access	Reset
0	OVERFLOWRESET	Register OverflowReset is a pulse register that clears overflow status bits per observed port on each write access. OverflowReset = nObservable. Writing 0x2 clears the overflow status of observed port 1.	RW	0x0

8.4.19.11. Probe_emacs_main_TransactionStatProfiler_PendingEventMode

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_TransactionStatProfiler	0xFFD14800	0xFFD14874

Offset: 0x74

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															PENDINGEVENTMODE RW 0x0

Probe_emacs_main_TransactionStatProfiler_PendingEventMode Fields

Bit	Name	Description	Access	Reset
0	PENDINGEVENTMODE	Register pendingEventMode is a 1-bit register that configures the pending event mode. When set to 0 (CYCLE), and when register mode is set to PENDING, the pending event is generated on each cycle when the counter is greater than zero. When set to 1 (STOP) the pending event is generated on each stop event.	RW	0x0

8.4.19.12. Probe_emacs_main_TransactionStatProfiler_PreScaler

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_TransactionStatProfiler	0xFFD14800	0xFFD14878

Offset: 0x78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								PRESCALER RW 0x0							

Probe_emacs_main_TransactionStatProfiler_PreScaler Fields

Bit	Name	Description	Access	Reset
7:0	PRESCALER	8Register Prescaler is an-bit pre-scaling register that accepts any pre-scaling value between 1 (default) and 256. If set to 0, pre-scaling is disabled. If set to any other supported value "n", the threshold counter value is divided by (n + 1).	RW	0x0

8.4.20. noc_mpu_m0_cs_obs_at_main_AtEndPoint Address Map

Module Instance	Base Address	End Address
i_noc_mpu_m0_cs_obs_at_main_AtEndPoint	0xFFD14900	0xFFD1497F

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

cs_obs_at_main_ErrorLogger_0_Id_RevisionId Fields

Bit	Name	Description	Access	Reset
31:8	FLEXNOCID	Field containing the build revision of the software used to generate the IP HDL code.	RO	0x129FF
7:0	USERID	Field containing a user defined value, not used anywhere inside the IP itself.	RO	0x0

8.4.21.4. cs_obs_at_main_ErrorLogger_0_FaultEn

Module Instance	Base Address	Register Address
i_noc_mpu_m0_cs_obs_at_main_ErrorLogger_0	0xFFD14980	0xFFD14988

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															FAULT EN RW 0x0

cs_obs_at_main_ErrorLogger_0_FaultEn Fields

Bit	Name	Description	Access	Reset
0	FAULTEN	Set to 1 to enable output signal Fault. Fault asserted when ErrVld is 1.	RW	0x0

8.4.21.5. cs_obs_at_main_ErrorLogger_0_ErrVld

Module Instance	Base Address	Register Address
i_noc_mpu_m0_cs_obs_at_main_ErrorLogger_0	0xFFD14980	0xFFD1498C

Offset: 0xC

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															ERRVLD D RO 0x0

cs_obs_at_main_ErrorLogger_0_ErrVld Fields

Bit	Name	Description	Access	Reset
0	ERRVLD	1 indicates an error has been logged	RO	0x0

8.4.21.6. cs_obs_at_main_ErrorLogger_0_ErrClr

Module Instance	Base Address	Register Address
i_noc_mpu_m0_cs_obs_at_main_ErrorLogger_0	0xFFD14980	0xFFD14990

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														ERRCLR RW 0x0	

cs_obs_at_main_ErrorLogger_0_ErrClr Fields

Bit	Name	Description	Access	Reset
0	ERRCLR	Set to 1 to clear ErrVld. NOTE The written value is not stored in ErrVld. A read always returns 0.	RW	0x0

8.4.21.7. cs_obs_at_main_ErrorLogger_0_ErrLog0

Stores NTP packet header fields Lock, Opc, ErrCode, Len1 and indicates version of NTP transport protocol

Module Instance	Base Address	Register Address
i_noc_mpu_m0_cs_obs_at_main_ErrorLogger_0	0xFFD14980	0xFFD14994

Offset: 0x14

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FORMA T RO 0x1	Reserved							LEN1 RO 0x0							
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved					ERRCODE RO 0x0			Reserved				OPC RO 0x0			LOCK RO 0x0

cs_obs_at_main_ErrorLogger_0_ErrLog0 Fields

Bit	Name	Description	Access	Reset
31	FORMAT	NTTP transport protocol version	RO	0x1
23:16	LEN1	Len1	RO	0x0
10:8	ERRCODE	ErrCode	RO	0x0
4:1	OPC	Opc	RO	0x0
0	LOCK	Lock	RO	0x0

8.4.21.8. cs_obs_at_main_ErrorLogger_0_ErrLog1

Module Instance	Base Address	Register Address
i_noc_mpu_m0_cs_obs_at_main_ErrorLogger_0	0xFFD14980	0xFFD14998

Offset: 0x18

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

8.4.22.4. Probe_MPU_main_Probe_MainCtl

Register MainCtl contains probe global control bits. The register has seven bit fields:

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_MPU_main_Probe	0xFFD15000	0xFFD15008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								FILTB YTEAL WAYSCH AINABLE EN	INTRU SIVEM ODE RO BLEEN RW 0x0	STATC ONDDU MP RW 0x0	ALARM EN RW 0x0	STATE N RW 0x0	PAYLO ADEN RW 0x0	TRACE EN RW 0x0	ERREN RW 0x0

Probe_MPU_main_Probe_MainCtl Fields

Bit	Name	Description	Access	Reset
7	FILTBYTEALWAYSCHAINABLEEN	When set to 0, filters are mapped to all statistic counters when counting bytes or enabled bytes. Therefore, only filter events mapped to even counters can be counted using a pair of chained counters. When set to 1, filters are mapped only to even statistic counters when counting bytes or enabled bytes. Thus events from any filter can be counted using a pair of chained counters.	RW	0x0
6	INTRUSIVEMODE	When set to 1, register field IntrusiveMode enables trace operation in Intrusive flow-control mode. When set to 0, the register enables trace operation in Overflow flow-control mode.	RO	0x0
5	STATCONDUMP	When set, register field StatCondDump enables the dump of a statistics frame to the range of counter values set for registers StatAlarmMin, StatAlarmMax, and AlarmMode. This field also renders register StatAlarmStatus inoperative. When parameter statisticsCounterAlarm is set to False, the StatCondDump register bit is reserved.	RW	0x0
continued...				

Bit	Name	Description	Access	Reset
4	ALARMEN	When set, register field AlarmEn enables the probe to collect alarm-related information. When the register field bit is null, both TraceAlarm and StatAlarm outputs are driven to 0.	RW	0x0
3	STATEN	When set to 1, register field StatEn enables statistics profiling. The probe sends statistics results to the output for signal ObsTx. All statistics counters are cleared when the StatEn bit goes from 0 to 1. When set to 0, counters are disabled.	RW	0x0
2	PAYLOADEN	Register field PayloadEn, when set to 1, enables traces to contain headers and payload. When set to 0, only headers are reported.	RW	0x0
1	TRACEEN	Register field TraceEn enables the probe to send filtered packets (Trace) on the ObsTx observation output.	RW	0x0
0	ERREN	Register field ErrEn enables the probe to send on the ObsTx output any packet with Error status, independently of filtering mechanisms, thus constituting a simple supplementary global filter.	RW	0x0

8.4.22.5. Probe_MPU_main_Probe_CfgCtl

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_MPU_main_Probe	0xFFD15000	0xFFD1500C

31:0	FILTERS_0_ADDRBASE_LOW	Address LSB register.	RW	0x0

8.4.22.20. Probe_MPU_main_Probe_Filters_0_WindowSize

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_MPU_main_P robe	0xFFD15000	0xFFD15054

Offset: 0x54

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										FILTERS_0_WINDOWSIZE RW 0x0					

Probe_MPU_main_Probe_Filters_0_WindowSize Fields

Bit	Name	Description	Access	Reset
5:0	FILTERS_0_WINDOWSIZE	Register WindowSize contains the encoded address mask used to filter packets. The effective Mask value is equal to $\sim(2^{\max(\text{WindowSize}, \text{packet.Len})} - 1)$. A packet is a candidate when $\text{packet.Addr} \& \text{Mask} = \text{AddrBase} \& \text{Mask}$. This allows filtering of packets having an intersection with the AddrBase/WindowSize burst aligned region, even if the region is smaller than the packet.	RW	0x0

8.4.22.21. Probe_MPU_main_Probe_Filters_0_SecurityBase

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_MPU_main_P robe	0xFFD15000	0xFFD15058

Offset: 0x58

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													FILTERS_0_SECURITYBASE RW 0x0		

Probe_MPU_main_Probe_Filters_0_SecurityBase Fields

Bit	Name	Description	Access	Reset
2:0	FILTERS_0_SECURITYBASE	Register SecurityBase contains the security base used to filter packets.	RW	0x0

8.4.22.22. Probe_MPU_main_Probe_Filters_0_SecurityMask

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_MPU_main_Probe	0xFFD15000	0xFFD1505C

Offset: 0x5C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													FILTERS_0_SECURITYMASK RW 0x0		

Probe_MPU_main_Probe_Filters_0_SecurityMask Fields

Bit	Name	Description	Access	Reset
2:0	FILTERS_0_SECURITYMASK	Register SecurityMask is contains the security mask used to filter packets. A packet is a candidate when: packet.Security & SecurityMask = SecurityBase & SecurityMasks.	RW	0x0

8.4.22.23. Probe_MPU_main_Probe_Filters_0_Opcode

Packet Probe register Opcode is a 4-bit register that selects candidate packets based on packet opcodes (0 disables the filter):

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_MPU_main_Probe	0xFFD15000	0xFFD15060

Offset: 0x60

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												URGEN RW 0x0	LOCKE N RW 0x0	WREN RW 0x0	RDEN RW 0x0

Probe_MPU_main_Probe_Filters_0_Opcode Fields

Bit	Name	Description	Access	Reset
3	URGEN	Selects URG packets (urgency).	RW	0x0
2	LOCKEN	Selects RDX-WR, RDL, WRC and Linked sequence.	RW	0x0
1	WREN	Selects WR packets.	RW	0x0
0	RDEN	Selects RD packets.	RW	0x0

8.4.22.24. Probe_MPU_main_Probe_Filters_0_Status

Register Status is 2-bit register that selects candidate packets based on packet status.

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_MPU_main_Probe	0xFFD15000	0xFFD15064

Offset: 0x64

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

fpga2sdram1_axi32_I_main_QosGenerator_Bandwidth Fields

Bit	Name	Description	Access	Reset
10:0	BANDWIDTH	In Bandwidth Limiter or Bandwidth Regulator mode, the bandwidth threshold is in units of 1/256th bytes per cycle. The formula to calculate this value is: Bandwidth = Throughput (Mbsp) * 256 / Clock Frequency. For example, 80 MBps on a 250 MHz interface has the value 0x0052 (BW = 80Mbps * 256 / 250MHz = 81.92, which is rounded to 0x0052).	RW	0x280

9. HPS-FPGA Bridges

This chapter describes the bridges in the hard processor system (HPS) used to communicate data between the FPGA fabric and HPS logic.

These bridges make use of Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) protocol, based on Arteris FlexNoC network-on-chip (NOC) interconnect IP.

The HPS contains the following HPS-FPGA bridges:

- FPGA-to-HPS Bridge
- HPS-to-FPGA Bridge
- Lightweight HPS-to-FPGA Bridge

Additional information is available in the AMBA AXI Protocol Specification v1.0, which you can download from the ARM Infocenter website.

9.1. Features of the HPS-FPGA Bridges

The HPS-FPGA bridges allow masters in the FPGA fabric to communicate with slaves in the HPS logic and vice versa. For example, if you implement memories or peripherals in the FPGA fabric, HPS components such as the MPU can access them. Components implemented in the FPGA fabric, such as the Nios® II processor, can also access memories and peripherals in the HPS logic.

Table 92. HPS-FPGA Bridge Features

Feature	FPGA-to-HPS Bridge	HPS-to-FPGA Bridge	Lightweight HPS-to-FPGA Bridge
Supports the AMBA AXI3 interface and FlexNoC low latency interface protocols	Y	Y	Y
Implements clock crossing and manages the transfer of data across the clock domains in the HPS logic and the FPGA fabric	Y	Y	Y
Performs data width conversion between the HPS logic and the FPGA fabric	Y	Y	Y
Allows configuration of FPGA interface widths at instantiation time	Y	Y	N

Each bridge consists of a master-slave pair with one interface exposed to the FPGA fabric and the other exposed to the HPS logic. The FPGA-to-HPS bridge exposes an AXI slave interface that you can connect to AXI or Avalon-MM master interfaces in the FPGA fabric. The HPS-to-FPGA and lightweight HPS-to-FPGA bridges expose an AXI master interface that you can connect to AXI or Avalon-MM slave interfaces in the FPGA fabric.

Information about configuring the AXI bridges

9.2. Arria 10 HPS-FPGA Bridges Block Diagram and System Integration

Figure 39. HPS-FPGA Bridge Connectivity

The following figure shows the HPS-FPGA bridges in the context of the FPGA fabric and the L3 interconnect to the HPS. Each master (M) and slave (S) interface is shown with its data width(s). The clock domain for each interconnect is shown in parentheses.

The HPS-to-FPGA and lightweight HPS-to-FPGA bridges are both mastered by the level 3 (L3) interconnect. The FPGA-to-HPS bridge masters the L3 interconnect. This arrangement allows any master implemented in the FPGA fabric to access most slaves in the HPS. For example, the FPGA-to-HPS bridge can access the accelerator coherency port (ACP) of the MPU subsystem to perform cache-coherent accesses to the SDRAM subsystem.

9.3. Functional Description of the HPS-FPGA Bridges

9.3.1. Functional Description of the FPGA-to-HPS Bridge

The FPGA-to-HPS bridge provides access to the peripherals in the HPS from the FPGA. This access is available to any master implemented in the FPGA fabric. You can configure the bridge slave, which is exposed to the FPGA fabric, to support the AXI protocol, with a data width of 32, 64 or 128 bits. The FPGA-to-HPS bridge multiplexes the configured data width from the L3 interconnect to the FPGA interface.

Table 93. FPGA-to-HPS Bridge Properties

The following table lists the properties of the FPGA-to-HPS bridge, including the configurable slave interface exposed to the FPGA fabric.

Bridge Property	Value
Data width ⁽¹⁹⁾	32, 64, or 128 bits
Clock domain	fpga2hps_clk
Byte address width	32 bits
ID width	4 bits
Read acceptance	8 transactions
Write acceptance	8 transactions
Total acceptance	16 transactions

The FPGA-to-HPS bridge is configurable in the HPS component parameter editor, available in Platform Designer and the IP Catalog. The HPS component parameter editor allows you to set the data path width and the bridge protocol, according to the FPGA bitstream.

Warning: To avoid memory aliasing issues, ensure that Avalon-MM burst transactions into the HPS do not cross the 4 KB address boundary restriction specified by the AXI protocol.

9.3.1.1. FPGA-to-HPS Access to ACP

When the error correction code (ECC) option is enabled in the level 2 (L2) cache controller, all accesses from the FPGA-to-HPS bridge to the ACP must be 64 bits wide and aligned on 8-byte boundaries after up- or downsizing takes place. Ensure that the address alignment is a multiple of 8 bytes and that (burst size) × (burst length) is a multiple of 8 bytes.

9.3.1.2. FPGA-to-HPS Bridge Slave Signals

The FPGA-to-HPS bridge slave address channels support user-sideband signals, routed to the ACP in the MPU subsystem. All the signals have a fixed width except the data and write strobes for the read and write data channels. The variable width signals depend on the data width setting of the bridge.

The FPGA-to-HPS bridge incorporates Arm's TrustZone technology by providing the `ARPROT[1]` and `AWPROT[1]` signals, which specify whether a transaction is secure or nonsecure. The firewall logic uses the `AxPROT` signals to determine if a bus transaction matches the security level allowed. You can program security values in the Secure Configuration Registers of the system interconnect.

⁽¹⁹⁾ The bridge slave data width is user-configurable at the time you instantiate the HPS component in your system.

All peripheral slaves and memories in the SoC are secure when they are released from reset.

The following tables list all the signals exposed by the FPGA-to-HPS slave interface to the FPGA fabric.

Table 94. FPGA-to-HPS Bridge Slave Write Address Channel Signals

Signal	Width	Direction	Description
AWID	8 bits	Input	Write address ID
AWADDR	32 bits	Input	Write address
AWLEN	4 bits	Input	Burst length
AWSIZE	3 bits	Input	Burst size
AWBURST	2 bits	Input	Burst type
AWLOCK	2 bits	Input	Lock type—Valid values are 00 (normal access) and 01 (exclusive access)
AWCACHE	4 bits	Input	Cache policy type
AWPROT	3 bits	Input	Protection type
AWVALID	1 bit	Input	Write address channel valid
AWREADY	1 bit	Output	Write address channel ready
AWUSER	5 bits	Input	User sideband signals

Table 95. FPGA-to-HPS Bridge Slave Write Data Channel Signals

Signal	Width	Direction	Description
WID	8 bits	Input	Write ID
WDATA	32, 64, or 128 bits	Input	Write data
WSTRB	4, 8, or 16 bits	Input	Write data strobes
WLAST	1 bit	Input	Write last data identifier
WVALID	1 bit	Input	Write data channel valid
WREADY	1 bit	Output	Write data channel ready

Table 96. FPGA-to-HPS Bridge Slave Write Response Channel Signals

More information about Secure Firewall Bus Transactions

9.3.2. Functional Description of the HPS-to-FPGA Bridge

The HPS-to-FPGA bridge provides a configurable-width, high-performance master interface to the FPGA fabric. The bridge provides most masters in the HPS with access to logic and peripherals implemented in the FPGA. The effective size of the address space is 0x3FFF0000, or 1 gigabyte (GB) minus the 64 megabytes (MB) occupied by peripherals, lightweight HPS-to-FPGA bridge, and on-chip RAM in the HPS. You can configure the bridge master exposed to the FPGA fabric for 32-, 64-, or 128-bit data. The amount of address space exposed to the MPU subsystem can also be reduced through the L2 cache address filtering mechanism.

The HPS-to-FPGA bridge multiplexes the configured data width from the L3 interconnect to the FPGA interface. The bridge provides width adaptation and clock crossing logic that allows the logic in the FPGA to operate in any clock domain, asynchronous from the HPS.

Warning: The HPS-to-FPGA bridge is accessed if the MPU boots from the FPGA. Before the MPU boots from the FPGA, the FPGA portion of the SoC device must be configured, and the HPS-to-FPGA bridge must be remapped into addressable space. Otherwise, access to the HPS-to-FPGA bridge during the boot process results in a bus error.

Table 99. HPS-to-FPGA Bridge Properties

The following table lists the properties of the HPS-to-FPGA bridge, including the configurable master interface exposed to the FPGA fabric.

Bridge Property	Value
Data width ⁽²⁰⁾	32, 64, or 128 bits
Clock domain	hps2fpga_clk
Byte address width	30 bits
ID width	4 bits
Read acceptance	16 transactions
Write acceptance	16 transactions
Total acceptance	16 transactions

The HPS-to-FPGA bridge is configurable in the HPS component parameter editor, available in Platform Designer and the IP Catalog. The HPS component parameter editor allows you to set the data path width and the bridge protocol, according to the FPGA bitstream.

9.3.3. Functional Description of the Lightweight HPS-to-FPGA Bridge

The lightweight HPS-to-FPGA bridge provides a lower-performance interface to the FPGA fabric. This interface is useful for accessing the control and status registers of soft peripherals. The bridge provides a 2 MB address space and access to logic, peripherals, and memory implemented in the FPGA fabric. The MPU subsystem, direct memory access (DMA) controller, and debug access port (DAP) can use the lightweight HPS-to-FPGA bridge to access the FPGA fabric or NoC registers.

The lightweight HPS-to-FPGA bridge has a fixed data width of 32 bits.

Use the lightweight HPS-to-FPGA bridge as a secondary, lower-performance master interface to the FPGA fabric. With a fixed width and a smaller address space, the lightweight bridge is useful for low-bandwidth traffic, such as memory-mapped register accesses to FPGA peripherals. This approach diverts traffic from the high-performance HPS-to-FPGA bridge, and can improve both register access latency and overall system performance.

Warning: Before the lightweight HPS-to-FPGA bridge can be accessed, the FPGA portion of the SoC device must be configured. Otherwise, accesses to the lightweight HPS-to-FPGA bridge will result in a bus error.

Table 105. Lightweight HPS-to-FPGA Bridge Properties

This table lists the properties of the lightweight HPS-to-FPGA bridge, including the master interface exposed to the FPGA fabric.

Bridge Property	Value
Data width	32 bits
Clock domain	lwh2fpga_clk
Byte address width	21 bits
ID width	4 bits
Read acceptance	16 transactions
Write acceptance	16 transactions
Total acceptance	16 transactions

The lightweight HPS-to-FPGA bridge is configurable in the HPS component parameter editor, available in Platform Designer and the IP Catalog. The HPS component parameter editor allows you to set the bridge protocol, according to the FPGA bitstream.

9.3.4. Clocks and Resets

9.3.4.1. FPGA-to-HPS Bridge Clocks and Resets

The master interface of the bridge in the HPS logic operates in the `l3_main_clk` clock domain. The slave interface exposed to the FPGA fabric operates in the `fpga2hps_clk` clock domain provided by the user logic. The bridge provides clock crossing logic that allows the logic in the FPGA to operate in any clock domain, asynchronous from the HPS.

The FPGA-to-HPS bridge has one reset signal, `fpga2hps_bridge_rst_n`. The reset manager drives this signal to the FPGA-to-HPS bridge on a cold or warm reset.

Related Information

9.3.4.2. HPS-to-FPGA Bridge Clocks and Resets

The master interface into the FPGA fabric operates in the `hps2fpga_clk` clock domain. The clock is provided by user logic. The slave interface of the bridge in the HPS logic operates in the `l3_main_clk` clock domain. The bridge provides clock crossing logic that allows the logic in the FPGA to operate in any clock domain, asynchronous from the HPS.

The HPS-to-FPGA bridge has one reset signal, `hps2fpga_bridge_rst_n`. The reset manager drives this signal to the HPS-to-FPGA bridge on a cold or warm reset.

Note:

Make sure that all transactions on the bridge are completed before shutting down and resetting the bridge. If the system is unable to meet this recommendation, the Arria 10 SoC device has a built-in timeout that can be enabled to force all outstanding transactions on the bridge to complete. The NoC timeout is enabled by setting the `en` bit in the System Manager's `noc_timeout` register. Ensure that the bridge operates at 100 MHz or faster when the NoC timeout is enabled. If the bridge is operating below 100 MHz, the timeout does not occur.

9.3.4.3. Lightweight HPS-to-FPGA Bridge Clocks and Resets

The master interface into the FPGA fabric operates in the `lwh2fpga_clk` clock domain. The clock is provided by custom logic in the FPGA fabric. The slave interface of the bridge in the HPS logic operates in the `l3_main_clk` clock domain. The bridge provides clock crossing logic that allows the logic in the FPGA to operate in any clock domain, asynchronous from the HPS.

The lightweight HPS-to-FPGA bridge has one reset signal, `lwhps2fpga_bridge_rst_n`. The reset manager drives this signal to the lightweight HPS-to-FPGA bridge on a cold or warm reset.

Note: Make sure that all transactions on the bridge are completed before shutting down and resetting the bridge. If the system is unable to meet this recommendation, the Arria 10 SoC device has a built-in timeout that can be enabled to force all outstanding transactions on the bridge to complete. The NoC timeout is enabled by setting the `en` bit in the System Manager's `noc_timeout` register. Ensure that the bridge operates at 100 MHz or faster when the NoC timeout is enabled. If the bridge is operating below 100 MHz, the timeout does not occur.

For information about the `noc_timeout` register, refer to the *System Manager* chapter.

9.3.4.4. Taking HPS-FPGA Bridges Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

9.3.5. Data Width Sizing

The HPS-to-FPGA and FPGA-to-HPS bridges allow 32-, 64-, and 128-bit interfaces to be exposed to the FPGA fabric. For 32-bit and 128-bit interfaces, the bridge performs data width conversion to the fixed 64-bit interface within the HPS. This conversion is called *upsizing* in the case of data being converted from a 64-bit interface to a 128-bit interface. It is called *downsizing* in the case of data being converted from a 64-bit interface to a 32-bit interface. If an exclusive access is split into multiple transactions, the transactions lose their exclusive access information.

During the upsizing or downsizing process, transactions can also be resized using a data merging technique. For example, in the case of a 32-bit to 64-bit upsizing, if the size of each beat entering the bridge's 32-bit interface is only two bytes, the bridge can merge up to four beats to form a single 64-bit beat. Similarly, in the case of a 128-bit to 64-bit downsizing, if the size of each beat entering the bridge's 128-bit interface is only four bytes, the bridge can merge two beats to form a single 64-bit beat.

9.3.5.1. Ready Latency Support

The HPS-to-FPGA and FPGA-to-HPS bridges support an optional ready latency feature, which allows your design to run at a higher F_{MAX} . When enabled, this feature adds a pipeline stage between the HPS and the FPGA fabric to improve ready/valid handshake timing. Enabling this feature entails a minimal increase in bridge latency.

You can enable this feature when you instantiate the HPS component in Platform Designer.

10. Cortex-A9 Microprocessor Unit Subsystem

The hard processor system (HPS) in the Intel SoC device includes a stand-alone, full-featured Arm Cortex-A9, dual-core 32-bit application processor. The Cortex-A9 microprocessor unit (MPU) subsystem is composed of a Cortex-A9 MPCore, a level 2 (L2) cache, and debugging modules.

Related Information

[Intel Arria 10 Hard Processor System Technical Reference Manual Revision History](#) on page 17

For details on the document revision history of this chapter

10.1. Features of the Cortex-A9 MPU Subsystem

The Intel Cortex-A9 MPU subsystem provides the following features:

- Two Arm Cortex-A9 processors, each with the following support modules:
 - Arm NEON single instruction, multiple data (SIMD) coprocessor
 - Memory Management Unit (MMU)
 - 32 KB instruction cache
 - 32 KB data cache
 - Private interval timer
 - Private watchdog timer
- Interrupt controller
- Global timer
- Snoop control unit (SCU)
- Accelerator Coherency Port (ACP)
- Arm L2 cache controller
- TrustZone system security extensions
- Symmetric multiprocessing (SMP) and asymmetric multiprocessing (AMP) modes
- Debugging modules

The Cortex-A9 MPU incorporates the following core and L2 cache versions:

Table 111. Cortex-A9 MPU Module Versions

Feature	Version
Cortex-A9 Core	r4p1
L2-310 Level 2 Cache Controller	r3p3

10.2. Cortex-A9 MPU Subsystem Block Diagram and System Integration

10.2.1. Cortex-A9 MPU Subsystem with System Interconnect

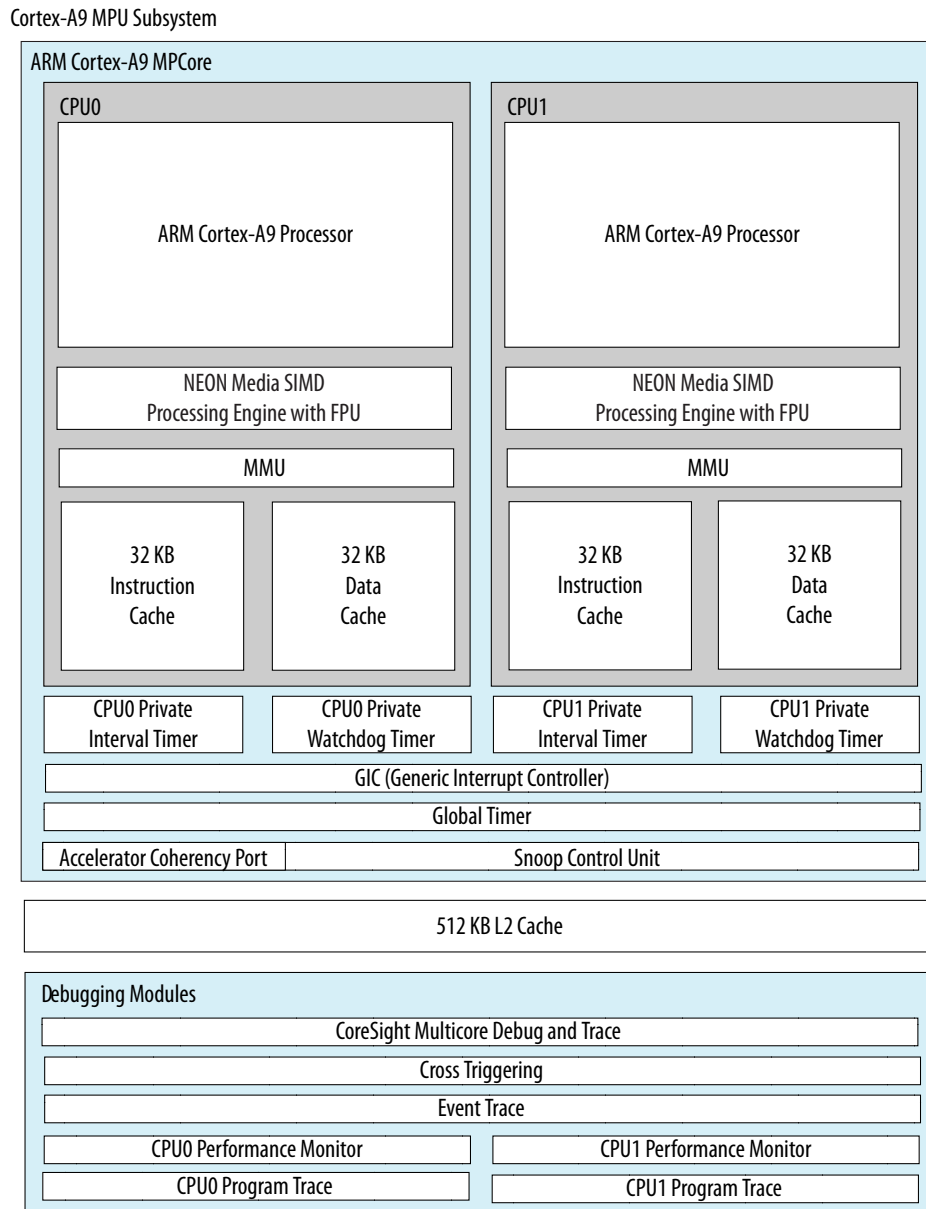

This block diagram shows a dual-core MPU subsystem in the context of the HPS, with the L2 cache. The L2 cache can access either the system interconnect or the SDRAM L3 Interconnect.

Figure 40. Cortex-A9 MPU Subsystem with Interconnect Block Diagram

10.2.2. Cortex-A9 MPU Subsystem Internals

Figure 41. Cortex-A9 MPU Subsystem Block Diagram

10.3. Cortex-A9 MPCore

The MPU subsystem includes a stand-alone, full-featured Arm Cortex-A9 MPCore dual-core 32-bit application processor. The processor, like other HPS masters, can access soft IP in the FPGA fabric through the HPS-to-FPGA bridges.

10.3.1. Functional Description

The Arm Cortex-A9 MPCore contains the following sub-modules:

- Two Cortex-A9 Revision r4p1 processors operating in SMP or AMP mode
- Snoop control unit (SCU)
- Private interval timer for each processor core
- Private watchdog timer for each processor core
- Global timer
- Interrupt controller

Each transaction originating from the Cortex-A9 MPU subsystem can be flagged as secure or non-secure.

10.3.2. Implementation Details

Table 112. Cortex-A9 MPCore Processor Configuration

This table shows the parameter settings for the Cortex-A9 MPCore.

Feature	Options
Cortex-A9 processors	2
Instruction cache size per Cortex-A9 processor	32 KB
Data cache size per Cortex-A9 processor	32 KB
TLB size per Cortex-A9 processor	512 entries
Media Processing Engine with NEON technology per Cortex-A9 processor ⁽²¹⁾	Included
Preload Engine per Cortex-A9 processor	Included
Number of entries in the Preload Engine FIFO per Cortex-A9 processor	16
Jazelle DBX extension per Cortex-A9 processor	Full
Program Trace Macrocell (PTM) interface per Cortex-A9 processor	Included
Support for parity error detection ⁽²²⁾	Included
Master ports	Two
Accelerator Coherency Port	Included

Related Information

10.3.3. Cortex-A9 Processor

Each Cortex-A9 processor includes the following hardware blocks:

- Arm NEON single instruction, multiple data (SIMD) coprocessor with vector floating-point (VFP) v3 double-precision floating point unit for media and signal processing acceleration
 - Single- and double-precision IEEE-754 floating point math support
 - Integer and polynomial math support
- Level 1 (L1) cache with parity checking
 - 32 KB four-way set-associative instruction cache
 - 32 KB four-way set-associative data cache
- CoreSight Program Trace Macrocell (PTM) supporting instruction trace

⁽²¹⁾ Includes support for floating-point operations.

⁽²²⁾ For a description of the parity error scheme and parity error signals, refer to the Cortex-A9 Technical Reference Manual, available on the Arm website (infocenter.arm.com).

Each Cortex-A9 processor supports the following features:

- Dual-issue superscalar pipeline with advanced branch prediction
- Out-of-order (OoO) dispatch and speculative instruction execution
- 2.5 million instructions per second (MIPS) per MHz, based on the Dhrystone 2.1 benchmark
- 2048-entry Branch Target Address Cache (BTAC)
- 512-entry translation lookaside buffer (TLB)
- 64-entry instruction micro-TLB
- TrustZone security extensions
- Configurable data endianness
- Jazelle* DBX Extensions for byte-code dynamic compiler support
- The Cortex-A9 processor architecture supports the following instruction sets:
 - The ARMv7-A performance-optimized instruction set
 - The memory-optimized Thumb*-2 mixed instruction set
 - Improves energy efficiency
 - 31% smaller memory footprint
 - 38% faster than the original Thumb instruction set
 - The Thumb instruction set—supported for legacy applications
- Each processor core in the Intel HPS includes an MMU to support the memory management requirements of common modern operating systems.

The Cortex-A9 processors are designated CPU0 and CPU1.

Related Information

[Arm Infocenter](#)

Detailed documentation of ARM Cortex-A9 series processors is available on the ARM Infocenter website.

10.3.3.1. Reset

When a cold or warm reset is issued in the MPU, CPU0 is released from reset automatically. If CPU1 is present, then its reset signals are left asserted when a cold or warm reset is issued. After CPU0 comes out of reset, it can deassert CPU1's reset signals by clearing the CPU1 bit in the MPU Module Reset (`mpumodrst`) register in the Reset Manager.

Related Information

[Reset Manager](#) on page 138

10.3.4. Interactive Debugging Features

Each Cortex-A9 processor has built-in debugging capabilities, including six hardware breakpoints (two with Context ID comparison capability) and four watchpoints. The interactive debugging features can be controlled by external JTAG tools or by processor-based monitor code.

Related Information

Arm Infocenter

For more information about the interactive debugging system, refer to the *Debug* chapter of the Cortex-A9 Technical Reference Manual, available on the ARM Infocenter website.

10.3.5. L1 Caches

Cache memory that is closely coupled with an associated processor is called level 1, or L1 cache. Each Cortex-A9 processor has two independent 32 KB L1 caches—one for instructions and one for data—allowing simultaneous instruction fetches and data access. Each L1 cache is four-way set associative, with 32 bytes per line, and supports parity checking.

Note: A parity error cannot be recovered and is indicated by one of the parity error interrupt signals. On a parity error interrupt, you can reset the system or perform further actions depending on the indication of the interrupt signals.

10.3.5.1. Cache Latency

Latency for cache hits and misses varies.

The latency for an L1 cache hit is 1 clock. The latency for an L1 cache miss and L2 cache hit is 6 clocks best case. Latency in the L2 cache can vary depending on other operations in the L2. Parity and ECC settings have no effect on latency. A single-bit ECC error is corrected during the L2 read, but is not re-written to the L2 RAM.

10.3.6. Preload Engine

The preload engine (PLE) is a hardware block that enables the L2 cache to preload selected regions of memory.

The PLE signals the L2 cache when a cache line is needed in the L2 cache, by making the processor data master port start fetching the data. The processor data master does not complete the fetch or return the data to the processor. However, the L2 cache can then proceed to load the cache line. The data is only loaded to the L2 cache, not to the L1 cache or processor registers.

The preload functionality is under software control. The following PLE control parameters must be programmed:

- Programmed parameters, including the following:
 - Base address
 - Length of stride
 - Number of blocks
- A valid bit
- TrustZone memory protection for the cache memory, with an NS (non-secure) state bit
- A translation table base (TTB) address
- An Address Space Identifier (ASID) value

Related Information

Arm Infocenter

For more information about the PLE, refer to the *Preload Engine* chapter of the *Cortex-A9 Technical Reference Manual*, available on the ARM Infocenter website.

10.3.7. Floating Point Unit

Each Arm Cortex-A9 processor includes full support for IEEE-754 floating point operations.

The floating-point unit (FPU) can execute half-, single-, and double-precision variants of the following operations:

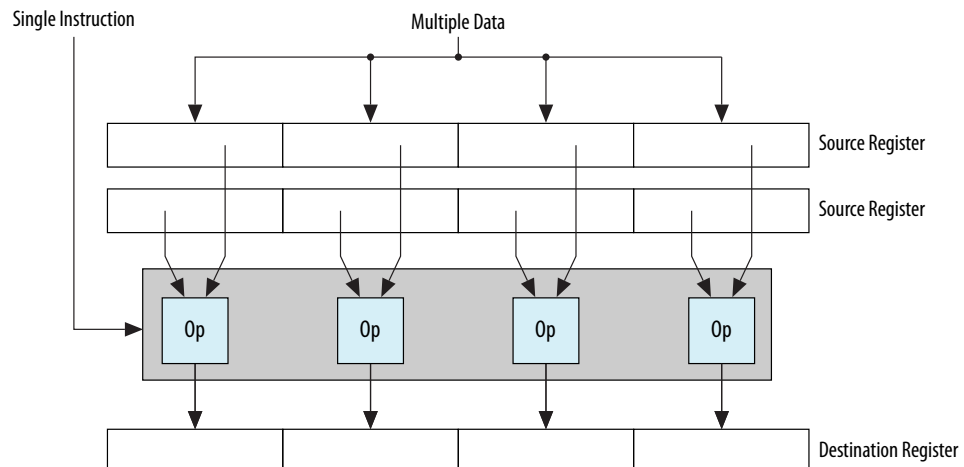

- Add
- Subtract
- Multiply
- Divide
- Multiply and accumulate (MAC)
- Square root

The FPU also converts between floating-point data formats and integers, including special operations to round towards zero required by high-level languages.

10.3.8. NEON Multimedia Processing Engine

The NEON multimedia processing engine (MPE) provides hardware acceleration for media and signal processing applications. Each CPU includes an Arm NEON MPE that supports SIMD processing.

10.3.8.1. Single Instruction, Multiple Data (SIMD) Processing

10.3.8.2. Features of the NEON MPE

The NEON processing engine accelerates multimedia and signal processing algorithms such as video encoding and decoding, 2-D and 3-D graphics, audio and speech processing, image processing, telephony, and sound synthesis.

The Cortex-A9 NEON MPE performs the following types of operations:

- SIMD and scalar single-precision floating-point computations
- Scalar double-precision floating-point computation
- SIMD and scalar half-precision floating-point conversion
- 8-, 16-, 32-, and 64-bit signed and unsigned integer SIMD computation
- 8-bit or 16-bit polynomial computation for single-bit coefficients

The following operations are available:

- Addition and subtraction
- Multiplication with optional accumulation (MAC)
- Maximum- or minimum-value driven lane selection operations
- Inverse square root approximation
- Comprehensive data-structure load instructions, including register-bank-resident table lookup

Related Information

[Arm Infocenter](#)

For more information about the Cortex-A9 NEON MPE, refer to the Cortex-A9 NEON Media Processing Engine Technical Reference Manual, which you can download from the ARM Infocenter website.

10.3.9. Memory Management Unit

The MMU is used in conjunction with the L1 and L2 caches to translate virtual addresses used by software to physical addresses used by hardware. Each processor has a private MMU.

10.3.9.1. TLBs Supported By the MMU

TLB Type	Memory Type	Number of Entries	Associativity
Micro TLB	Instruction	64	Fully associative
Micro TLB	Data	64	Fully associative
Main TLB	Instruction and Data	512	Two-way associative

10.3.9.2. TLB Features

The main TLB has the following features:

- Lockable entries using the lock-by-entry model
- Supports hardware page table walks to perform look-ups in the L1 data cache

The MPU address map is divided into the following regions:

- The boot region
- The SDRAM region
- The FPGA slaves region
- The HPS peripherals region

Note: The SMP bit in the ACTLR register must be set before enabling the MMU.

Related Information

- [Arm Infocenter](#)
For more information about the MMU, refer to the *Memory Management Unit* chapter of the *Cortex-A9 Technical Reference Manual*, available on the ARM Infocenter website.
- [Cortex-A9 MPCore Technical Reference Manual](#)
For more further information about the ACTLR register, refer to the *Cortex-A9 MPCore Technical Reference Manual*, available on the ARM Infocenter website.

10.3.9.3. The Boot Region

The boot region is 1 MB in size, based at address 0. After power-on, or after reset of the system interconnect, the boot region is occupied by the boot ROM, allowing the Cortex-A9 MPCore to boot. Although the boot region size is 1 MB, accesses beyond 128 KB are illegal because the boot ROM is only 128 KB.

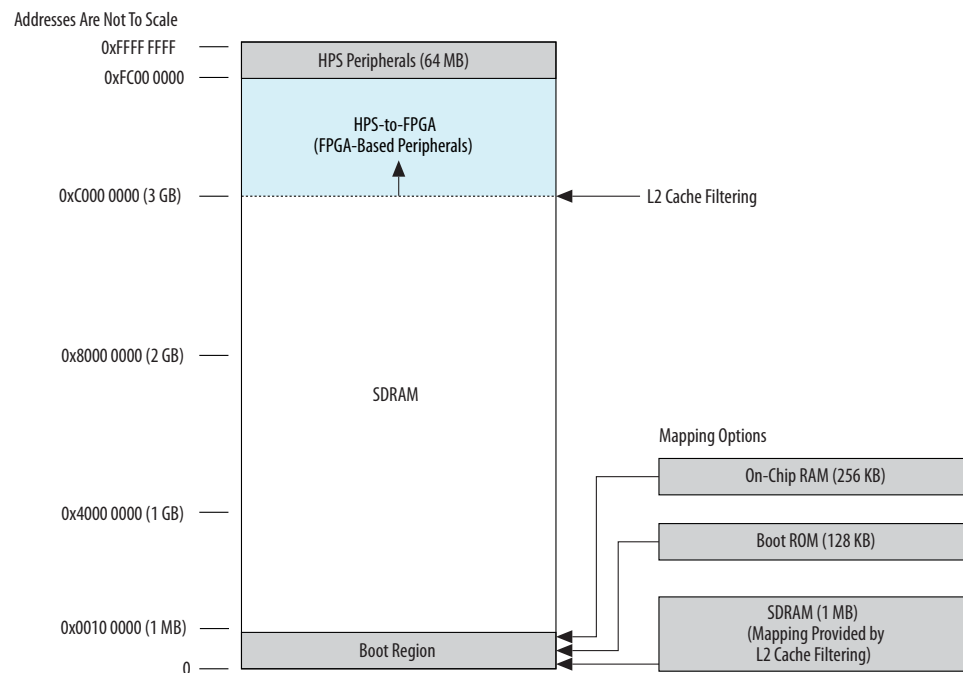

The 1 MB boot region can be subsequently remapped to the bottom 1 MB of SDRAM region by adjusting the L2 cache address filter.

Note: Alternatively, the boot region can be mapped to the 256 KB on-chip RAM.

Related Information

- [Address Remapping](#) on page 383
For more information about address remapping
- [System Interconnect](#) on page 364

10.3.9.3.1. Boot ROM Mapping

10.3.9.4. The SDRAM Region

The SDRAM region starts at address 0x100000 (1 MB). The top of the region is determined by the L2 cache filter.

The L2 cache contains a filtering mechanism that routes accesses to the SDRAM L3 interconnect and system interconnect. The filter defines a filter range with start and end addresses. Any access within this filter range is routed to the SDRAM L3 interconnect. Accesses outside of this filter range are routed to the system interconnect.

The start and end addresses are specified in the following register fields:

- `reg12_addr_filtering_start.address_filtering_start`
- `reg12_address_filtering_end.address_filtering_end`

To remap the lower 1MB of SDRAM into the boot region, set the filter start address to 0x0 to ensure accesses between 0x0 and 0xFFFF FFFF are routed to the SDRAM. Independently, you can set the filter end address in 1 MB increments above 0xC0000000 to extend the upper bounds of the SDRAM region. However, you achieve this extended range at the expense of the FPGA peripheral address span. Depending on the address filter settings in the L2 cache, the top of the SDRAM region can range from 0xBFFFFFFF to 0xFBFFFFFFF.

Related Information

[L2 Cache](#) on page 1048

10.3.9.5. The FPGA Slaves Region

The Cortex-A9 MPU subsystem supports the variable-sized FPGA slaves region to communicate with FPGA-based peripherals. This region can start as low as 0xC0000000, depending on the L2 cache filter settings. The top of the FPGA slaves region is located at 0xFBFFFFFF. As a result, the size of the FPGA slaves region can range from 0 to 0x3C000000 bytes.

10.3.9.6. The HPS Peripherals Region

The HPS peripherals region is the top 64 MB in the address space, starting at 0xFC000000 and extending to 0xFFFFFFFF. The HPS peripherals region is always allocated to the HPS dedicated peripherals for the Cortex-A9 MPU subsystem.

10.3.10. Performance Monitoring Unit

Each Cortex-A9 processor has a Performance Monitoring Unit (PMU). The PMU supports 58 events to gather statistics on the operation of the processor and memory system. Six counters in the PMU accumulate the events in real time. The PMU counters are accessible either from the processor itself, using the Coprocessor 14 (CP14) interface, or from an external debugger. The events are also supplied to the PTM and can be used for trigger or trace.

Related Information

Arm Infocenter

For more information about the PMU, refer to the *Performance Monitoring Unit* chapter of the *Cortex-A9 Technical Reference Manual*, available on the ARM Infocenter website.

10.3.11. Arm Cortex-A9 MPCore Timers

There is one interval timer and one watchdog timer for each processor.

10.3.11.1. Functional Description

Each timer is private, meaning that only its associated processor can access it. If the watchdog timer is not needed, it can be configured as a second interval timer.

Each private interval and watchdog timer has the following features:

- A 32-bit counter that optionally generates an interrupt when it reaches zero
- Configurable starting values for the counter
- An eight-bit prescaler value to qualify the clock period

10.3.11.2. Implementation Details

The timers are configurable to either single-shot or auto-reload mode. The timer blocks are clocked by `mpu_periph_clk` running at ¼ the rate of the `mpu_clk`.

Related Information

Arm Infocenter

For more information about private timers, refer to “About the private timer and watchdog blocks” in the *Global timer, Private timers, and Watchdog registers*

chapter of the *Cortex-A9 MPCore Technical Reference Manual*, available on the ARM Infocenter website.

10.3.12. Generic Interrupt Controller

10.3.12.1. Functional Description

The PL390 Generic Interrupt Controller (GIC) supports up to 128 interrupt sources, including dedicated peripherals and IP implemented in the FPGA fabric. In a dual-core system, the GIC is shared by both Cortex-A9 processors. Each processor also has 16 banked software-generated interrupts and 16 banked private peripheral interrupts, which occupy GIC interrupt numbers 0 to 31.

10.3.12.2. Implementation Details

The configuration and control for the GIC is memory-mapped and accessed through the SCU. The GIC are clocked by `mpu_periph_clk`, running at ¼ the rate of `mpu_clk`.

10.3.13. Global Timer

The MPU features a global 64-bit, auto-incrementing timer, which is primarily used by the operating system.

10.3.13.1. Functional Description

The global timer is accessible by the processors using memory-mapped access through the SCU. The global timer has the following features:

- 64-bit incrementing counter with an auto-incrementing feature. It continues incrementing after sending interrupts.
- Memory-mapped in the private memory region.
- Accessed at reset in Secure State only. It can only be set once, but secure code can read it at any time.
- Accessible to both Cortex-A9 processors in the MPCore.
- Clocked by mpu_periph_clk, running at ¼ the rate of mpu_clk.

10.3.13.2. Implementation Details

Each Cortex-A9 processor has a private 64-bit comparator that generates a private interrupt when the counter reaches the specified value. Each Cortex-A9 processor uses the banked ID, ID27, for this interrupt. ID27 is sent to the GIC as a Private Peripheral Interrupt (PPI).

The global timer is clocked by mpu_periph_clk, running at ¼ the rate of mpu_clk.

Related Information

Arm Infocenter

For more information about the global timer, refer to “About the Global Timer” in the *Global timer, Private timers, and Watchdog registers* chapter of the Cortex-A9 MPCore Technical Reference Manual, available on the ARM Infocenter website.

10.3.14. Snoop Control Unit

The SCU manages data traffic for the Cortex-A9 processors and the memory system, including the L2 cache. In a multi-master system, the processors and other masters can operate on shared data. The SCU ensures that each processor operates on the most up-to-date copy of data, maintaining cache coherency.

10.3.14.1. Functional Description

The SCU is used to connect the Cortex-A9 processors and the ACP to the L2 cache controller. The SCU performs the following functions:

- When the processors are set to SMP mode, the SCU maintains data cache coherency between the processors.
- Note:* The SCU does not maintain coherency of the instruction caches.
- Initiates L2 cache memory accesses
- Arbitrates between processors requesting L2 access
- Manages ACP access with cache coherency capabilities.

Related Information

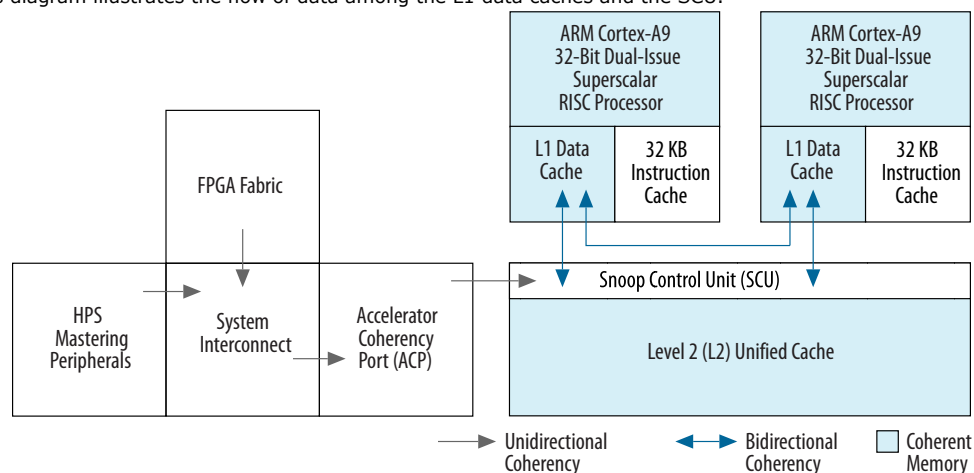

Arm Infocenter

For more information about the SCU, refer to the *Snoop Control Unit* chapter of the *Cortex-A9 MPCore Technical Reference Manual*, available on the ARM Infocenter website.

10.3.14.1.1. Coherent Memory, Snoop Control Unit, and Accelerator Coherency Port

Figure 42. Data Flow Between L1 Caches and SCU

This diagram illustrates the flow of data among the L1 data caches and the SCU.

Related Information

[Accelerator Coherency Port](#) on page 1043

10.3.14.2. Implementation Details

When the processor writes to any coherent memory location, the SCU ensures that the relevant data is coherent (updated, tagged or invalidated). Similarly, the SCU monitors read operations from a coherent memory location. If the required data is already stored within the other processor's L1 cache, the data is returned directly to the requesting processor. If the data is not in L1 cache, the SCU issues a read to the L2 cache. If the data is not in the L2 cache memory, the read is finally forwarded to main memory. The primary goal is to maximize overall memory performance and minimize power consumption.

The SCU maintains bidirectional coherency between the L1 data caches belonging to the processors. When one processor performs a cacheable write, if the same location is cached in the other L1 cache, the SCU updates it.

Non-coherent data passes through as a standard read or write operation.

The SCU also arbitrates between the Cortex-A9 processors if both attempt simultaneous access to the L2 cache, and manages accesses from the ACP.

10.3.15. Accelerator Coherency Port

The ACP allows master peripherals—including FPGA-based master peripherals—to maintain data coherency with the Cortex-A9 MPCore processors and the SCU. Dedicated master peripherals in the HPS, and those built in FPGA logic, access the coherent memory through the ACP. Cacheable master accesses from the system interconnect are redirected to the ACP.

The ACP port allows one-way coherency. One-way coherency allows an external ACP master to see the coherent memory of the Cortex-A9 processors but does not allow the Cortex-A9 processors to see memory changes outside of the cache.

A master on the ACP port can read coherent memory directly from the L1 and L2 caches, but cannot write directly to the L1 cache. The possible ACP master read and write scenarios are as follows:

- ACP master read with coherent data in the L1 cache: The ACP gets data directly from the L1 cache and the read is interleaved with a processor access to the L1 cache.
- ACP master read with coherent data in L2 cache: The ACP request is queued in the SCU and the transaction is sent to the L2 cache.
- ACP master read with coherent data not in L1 or L2 cache: Depending on the previous state of the data, the L1 or L2 cache may request the data from the L3 system interconnect. The ACP is stalled until data is available, however ACP support of multiple outstanding transactions minimizes bottlenecks.

- ACP master write with coherent data in the L1 cache: The L1 cache data is marked as invalid in the Cortex-A9 MPU and the line is evicted from the L1 cache and sent to L2 memory. The ACP write data is scheduled in the SCU and is eventually written to the L2 cache. Later, when the Cortex-A9 processor accesses the same memory location, a cache miss in the L1 occurs.
- ACP master write, with coherent data in the L2 cache: The ACP write is scheduled in the SCU and then is written into the L2 cache.
- ACP master write, with coherent data not in L1 or L2 cache: ACP write is scheduled.

An ACP transaction is generated when a master on the system interconnect has its `AxCACHE[1]` attribute signal set to 1, which indicates a coherent request. All transactions that are set as cacheable are routed to the ACP instead of the normal mapping and are treated as coherent by the cache controllers of the MPU subsystem. The ACP ID generation follows an allocation mechanism that ensures that requests with the same master initiator flow and sequence identifiers always allocate the same local sequence ID and that requests with different identifiers always have different IDs. In addition, if an allocator runs out of sequence IDs, the ACP stalls requests until the reception of responses makes new sequence IDs available. Therefore, the guaranteed number of pending transactions that the interconnect can have is up to four pending transactions, with the allowed AXI ID[2:0] values of 0x4 through 0x7. AXID[2:0] values of 0x0 and 0x1 are assigned to CPU0 and CPU1, respectively.

Note: The entire 4 GB address space can be accessed coherently through the ACP.

Note: Refer to the Arria 10 SoC device errata for details on Arm errata that directly affect the ACP.

10.3.15.1. AxUSER and AxCACHE Attributes

ARUSER[0] and AWUSER[0] Bits

The ACP distinguishes between shared and non-shared requests with the `ARUSER[0]` and `AWUSER[0]` signals. The other `AxUSER` signals, `AxUSER[4:1]` are not interpreted by the SCU and are simply forwarded to the L2 cache. They are typically set to `AxUSER[4:1] = b'1111`. The `AxCACHE[1]` attribute signals must also be set to allow L1 caches to be snooped. Sideband signals `ARUSER[4:1]` and `AWUSER[4:1]` convey the inner cache attributes.

The table below shows how the `AxUSER[0]` bit determines whether a request is shared or non-shared. `ARUSER[0]` applies to read transactions, and `AWUSER[0]` applies to write transactions.

Table 114. ARUSER[0] or AWUSER[0] Sideband Signal Information

ARUSER[0] or AWUSER[0]	Sideband Signal Information
1	Shared request
0	Non-shared request

Other AxUSER bits from the ACP are not interpreted by the SCU but are forwarded to the L2 cache.

ARCACHE[4:0] and AWCACHE[4:0] Bits

The Cortex-A9 MPU only interprets ARCACHE[1] and AWCACHE[1] from ACP requests. All other attributes are forwarded to the L2 cache. AxCACHE[1] is used in combination with AxUSER[0] to detect a coherent access. If AxCACHE[1]=0x1, (normal memory) and AxUSER[0]=0x1, then the access is considered coherent. All ACP requests with AxCACHE[1]=0x0 or AxUSER[0]=0x0 are seen as non-coherent requests.

Table 115. ARUSER[0] or AWUSER[0] Sideband Signal Information

ARCACHE[1] or AWCACHE[1]	ARUSER[0] or AWUSER[0]	Access Type
1	1	Coherent request
0	0	Non-coherent request

10.3.15.2. Cache Coherency for ACP Shared Requests

When a shared access is received on the ACP, caches are checked for coherency of the requested address. A shared access occurs when two masters access the same memory space.

This coherency check is performed by the SCU. If a cache hit occurs during a write access, the affected cache lines are cleaned and invalidated. This event may cause an eviction from the L1 cache to be sent to L2 memory if the L1 cache line is dirty. Once the invalidation and possible eviction is completed, the ACP write request is written to L2 memory. If an eviction was executed from L1 cache, then two consecutive writes to L2 memory occur over the AXI bus: the write from the eviction and the write from the ACP.

For a cache hit during a read access, the L1 cache line is provided by the CPU and is returned to the ACP.

For a cache miss during a write access, the invalidation is considered as complete and the ACP request is sent to L2 memory.

For a cache miss during a read access, the request is forwarded to L2 memory, which returns the data directly to the ACP.

Note: Shared write requests are always transferred to the L2 memory once the cache line is potentially clean and invalidated in the L1 cache memory. Reads are observed on the L2 only if they miss in the L1 cache.

10.3.15.3. AXI Master Configuration for ACP Access

To use the ACP for coherent accesses, the following configurations apply:

ACP master configurations must be as follows:

- For coherent ACP read accesses, the AXI bits must be programmed as follows to avoid compromising coherency:
 - `AxCACHE[3:0]` attributes must match the properties defined in the Cortex-A9 MPCore MMU page tables for the relevant memory region.
 - Shareable attribute `AxUSER[0]` must be set to 0x1

The Cortex-A9 MPCore configuration for ACP use should be as follows:

- The Snoop Control Unit must be enabled (by setting the SCU enable bit in the SCU Control Register at 0xFFFFC000).
- Coherent memory must be marked cacheable and shareable.
- The `SMP` bit of the `ACTLR` register must be set in the Cortex-A9 processor that shares data over the ACP.

Note:

To achieve maximum performance on the ACP, avoid switching from shared to non-shared requests and vice-versa. When a shared request is latched in the ACP and there are non-shared requests still pending, the non-shared requests must be completed before the shared request can proceed.

The following sections detail the attribute configurations necessary to support coherency.

10.3.15.3.1. Configuring `AxCACHE[3:0]` Sideband Signals for Coherent Accesses

The following list highlights how to correctly derive and apply the correct `AxCACHE` settings for coherent accesses.

- The correct `AxCACHE[3:0]` setting is dependent on the MMU page table settings. However, for coherent accesses, `AxCACHE[1]` must be set to 0x1.
- For HPS masters, `AxCACHE[3:0]` is static and applied to the relevant master port through the System Manager.
- For FPGA masters, `AxCACHE[3:0]` is applied in the FPGA fabric and can be set for each access.

Related Information

- [System Manager](#) on page 244
For more information about programming `AxCACHE[3:0]` through the System Manager

For more information about the Accelerator Coherency Port.

10.3.15.3.2. Configuring AxUSER[4:0] Sideband Signals

The following list highlights how to correctly derive and apply the correct AxUSER settings for coherent accesses.

- AxUSER[0] (shared attribute) must be set to 0x1 for coherent accesses.
- Because the ACP has no inner cache policy, AxUSER[3:1] is not interpreted by the SCU. AxUSER[3:1] attributes pass to the L2 cache controller and are used when the cache is operating in exclusive mode.
- For FPGA masters, AxUSER[4:0] is applied in the FPGA fabric and can be set for each access.

Related Information

[Cortex-A9 MPCore Technical Reference Manual](#)
For more information about the Accelerator Coherency Port.

10.3.15.4. Burst Sizes and Byte Strokes

The ACP improves system performance for hardware accelerators in the FPGA fabric. However, in order to achieve high levels of performance, you must use the one of the optimized burst types. Other burst configurations have significantly lower performance.

10.3.15.4.1. Recommended Burst Types

Table 116. Recommended Burst Types for Optimized Bursts

Burst Type	Beats	Width (Bits)	Address Type	Byte Strokes
Wrapping	4	64	64-bit aligned	Asserted
Incrementing	4	64	32-bit aligned	Asserted

Note: If the slave port of the FPGA-to-HPS bridge is not 64 bits wide, you must supply bursts to the FPGA-to-HPS bridge that are upsized or downsized to the burst types above. For example, if the slave data width of the FPGA-to-HPS bridge is 32 bits, then bursts of eight beats by 32 bits are required to access the ACP efficiently.

Note: If the address and burst size of the transaction to the ACP matches either of the conditions shown in the table "Recommended Burst Types for Optimized Bursts", the logic in the MPU assumes the transaction has all its byte strokes set. If the byte strokes are not all set, then the write does not actually overwrite all the bytes in the word. Instead, the cache assumes the whole cache line is valid. If this line is dirty (and therefore gets written out to SDRAM), data corruption might occur.

In addition to optimizing performance, using a 64-bit access width will allow you to use ECC. ECC is only supported for 64-bit accesses that are 64-bit aligned..

Related Information

[Single Event Upset Protection](#) on page 1051

10.3.15.5. Exclusive and Locked Accesses

The ACP does not support exclusive accesses to coherent memory. To ensure mutually exclusive access to shared data, use the exclusive access support built into the SDRAM L3 interconnect scheduler. The AXI buses that interface to the scheduler provide `ARLOCK[0]` and `AWLOCK[0]` signals which are used by the scheduler to arbitrate for exclusive access to a memory location. The SDRAM L3 scheduler contains one monitor for each of the following exclusive-capable masters:

- CPU0
- CPU1
- FPGA-to-HPS
- FPGA-to-SDRAM0
- FPGA-to-SDRAM1
- FPGA-to-SDRAM2

Each monitor only tracks one exclusive address.

Related Information

[System Interconnect](#) on page 364

To learn more about Exclusive Monitors in the System Interconnect, refer to the System Interconnect Chapter.

10.4. L2 Cache

The MPU subsystem includes a secondary 512 KB L2 shared, unified cache memory.

10.4.1. Functional Description

The L2 cache is much larger than the L1 cache. The L2 cache has significantly lower latency than external memory. The L2 cache is up to eight-way associative, configurable down to one-way (direct mapped). Like the L1 cache, the L2 cache can be locked by cache line, locked by way, or locked by master (CPU and ACP masters).

The L2 cache implements error correction codes (ECCs) and ECC error reporting. The cache can report a number of events to the processor and operating system.

Related Information

[Cortex-A9 MPU Subsystem Register Implementation](#) on page 1059

For more information regarding the L2 Cache Controller Address Map, refer to the *Cortex-A9 MPU Subsystem Register Implementation* section.

10.4.1.1. Cache Controller Configuration

The L2 cache consists of the Arm L2C-310 L2 cache controller configured as follows:

- 512 KB total memory
- Eight-way associativity
- Physically addressed, physically tagged
- Line length of 32 bytes
- Critical first word linefills

- Support for all AXI cache modes
 - Write-through
 - Write-back
 - Read allocate
 - Write allocate
 - Read and write allocate
- Single event upset (SEU) protection
 - Parity on Tag RAM
 - ECC on L2 Data RAM
- Two slave ports mastered by the SCU
- Two master ports connected to the following slave ports:
 - SDRAM L3 interconnect, 64-bit slave port width
 - L3 interconnect, 64-bit slave port width
- Cache lockdown capabilities as follows:
 - Line lockdown
 - Lockdown by way
 - Lockdown by master (both processors and ACP masters)
- TrustZone support
- Cache event monitoring

10.4.1.1.1. Implementation Details

The following table shows the parameter settings for the cache controller.

Table 117. Cache Controller Configuration

Feature	Meaning
Cache way size	64 KB
Number of cache ways	8 ways
Tag RAM write latency	1
Tag RAM read latency	1
Tag RAM setup latency	1
Data RAM write latency	1
<i>continued...</i>	

Feature	Meaning
Data RAM read latency	2
Data RAM setup latency	1
Parity logic	Parity logic enabled
Lockdown by master	Lockdown by master enabled
Lockdown by line	Lockdown by line enabled
AXI ID width on slave ports	6 AXI ID bits on slave ports
Address filtering	Address filtering logic enabled
Speculative read	Logic for supporting speculative read enabled
Presence of ARUSERMx and AWUSERMx sideband signals	Sideband signals enabled

Related Information

Arm Infocenter

For further information about cache controller configurable options, refer to the CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual, available on the ARM Infocenter website.

L2 Cache Event Monitoring

The L2 cache supports the built-in cache event monitoring signals shown in the table below. The L2 cache can count two of the events at any one time.

Table 118. L2 Cache Events

Event	Description
CO	Eviction (cast out) of a line from the L2 cache.
DRHIT	Data read hit in the L2 cache.
DRREQ	Data read lookup to the L2 cache. Subsequently results in a hit or miss.
DWHIT	Data write hit in the L2 cache.
DWREQ	Data write lookup to the L2 cache. Subsequently results in a hit or miss.
DWTREQ	Data write lookup to the L2 cache with write-through attribute. Subsequently results in a hit or miss.
EPFALLOC	Prefetch hint allocated into the L2 cache.
EPFHIT	Prefetch hint hits in the L2 cache.
EPFRCVDS0	Prefetch hint received by slave port S0.
EPFRCVDS1	Prefetch hint received by slave port S1.
IPFALLOC	Allocation of a prefetch generated by L2 cache controller into the L2 cache.
IRHIT	Instruction read hit in the L2 cache.
IRREQ	Instruction read lookup to the L2 cache. Subsequently results in a hit or miss.
SPNIDEN	Secure privileged non-invasive debug enable.
SRCONFS0	Speculative read confirmed in slave port S0.
SRCONFS1	Speculative read confirmed in slave port S1.
continued...	

Event	Description
SRRCVDS0	Speculative read received by slave port S0.
SRRCVDS1	Speculative read received by slave port S1.
WA	Allocation into the L2 cache caused by a write (with write-allocate attribute) miss.

In addition, the L2 cache events can be captured and timestamped using dedicated debugging circuitry.

Related Information

Arm Infocenter

For more information about L2 event capture, refer to the *Debug* chapter of the Cortex-A9 MPCore Technical Reference Manual, available on the ARM Infocenter website.

10.4.1.2. Single Event Upset Protection

The L2 cache has the option of using ECCs to protect against Single Event Upset (SEU) errors in the cache RAM.

The L2 cache has two types of protection:

- The L2 cache tag RAMs are protected by parity.
- The L2 cache data RAMs are protected using single error correction, double error detection (SECDED) ECC Hamming code.

Enabling ECCs does not affect the performance of the L2 cache. The ECC bits are calculated only for writes to the data RAM that are 64 bits wide (8 bytes, or one-quarter of the cache line length). The ECC logic does not perform a read-modify-write when calculating the ECC bits.

The ECC protection bits are not valid in the following cases:

- Data is written that is not 64-bit aligned in memory
- Data is written that is less than 64 bits in width

In these cases the Byte Write Error interrupt is asserted. Cache data is still written when such an error occurs. However, the ECC error detection and correction continues to function. Therefore, the cache data is likely to be incorrect on subsequent reads.

To use ECCs, the software and system must meet the following requirements:

- L1 and L2 cache must be configured as write-back and write-allocate for any cacheable memory region
- Level 3 interconnect masters using the ACP must only perform the following types of data writes:
 - 64-bit aligned in memory
 - 64-bit wide accesses

Note that system interconnect masters can include masters in the FPGA accessing the FPGA-to-HPS bridge.

If a correctable ECC error occurs, the ECC corrects the read data in parallel to asserting a correctable error signal on the AXI bus. If an uncorrectable error occurs in the L2 cache, the uncorrected data remains in the L2 cache and an AXI slave error (SLVERR) is sent to the L1 memory system. In addition, interrupts can be enabled for correctable and uncorrectable ECC errors through the GIC.

Related Information

[System Manager](#) on page 244

For more information about SEU errors, refer to the *System Manager* chapter.

10.4.1.3. L2 Cache Parity

Because the L2 data RAM is ECC-protected, parity checking on the data RAM is not required. However, because the tag RAM is not ECC protected, it requires parity checking. Because parity cannot be configured independently, parity checking for both the data RAM and tag RAM must be enabled.

Ideally, parity should be enabled before the L2 cache is enabled. If the cache is already enabled, you must clean the cache and disable it before parity is enabled. After enabling parity, the cache is invalidated and enabled. To enable parity:

1. Set the `Parity_on` bit in the `L2 Auxiliary Control` register.
2. Invalidate the L2 cache through the `Cache Maintenance Operations` registers.
3. Enable the cache through the `L2_Cache_enable` bit of the `L2 Control` register.

Note:

If you would like the parity errors to be reported you must enable the parity interrupts in the `L2 Interrupt Mask` register along with the corresponding interrupts in the general interrupt controller (GIC).

Refer to the Arm Infocenter website for more information regarding L2 cache registers and programming.

Parity Error Handling

If a parity error occurs in the tag or data RAM during AXI read transactions, a SLVERR response is reported through the event bus and interrupt signals. If a parity error occurs on tag or data RAM during AXI write transactions, a SLVERR response is reported back through a SLVERRINTR interrupt signal. For cache maintenance operations, if a parity error occurs on tag or data RAM, the error is reported back through the interrupt lines only. In addition, the L2 Cache cannot refill a line from external memory due to a parity error.

Related Information

[Arm Infocenter](#)

10.4.1.4. L2 Cache Lockdown Capabilities

The L2 cache has three methods to lock data in the cache RAMs:

- Lockdown by line—Used to lock lines in the cache. This is commonly used for loading critical sections of software into the cache temporarily.
- Lockdown by way—Allows any or all of the eight cache ways to be locked. This is commonly used for loading critical data or code into the cache.
- Lockdown by master-- allows cache ways to be dedicated to a single master port. This allows a large cache to look like smaller caches to multiple master ports. The L2 cache can be mastered by any of the L3 masters (including the FPGA fabric). When using lockdown by master, AXI ID0 and 1 represent CPU0 and CPU1 respectively and AXI IDs 0x4 through 0x7 can be used for the L3 interconnect masters.

Related Information

Arm Infocenter

For more information about L2 cache lockdown capabilities, refer to “Cache operation” in the *Functional Overview* chapter of the *CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual*, available on the ARM Infocenter website.

10.4.1.5. L2 Cache Event Monitoring

The L2 cache supports the built-in cache event monitoring signals shown in the table below. The L2 cache can count two of the events at any one time.

Table 119. L2 Cache Events

Event	Description
CO	Eviction (cast out) of a line from the L2 cache.
DRHIT	Data read hit in the L2 cache.
DRREQ	Data read lookup to the L2 cache. Subsequently results in a hit or miss.
DWHIT	Data write hit in the L2 cache.
DWREQ	Data write lookup to the L2 cache. Subsequently results in a hit or miss.
DWTREQ	Data write lookup to the L2 cache with write-through attribute. Subsequently results in a hit or miss.
EPFALLOC	Prefetch hint allocated into the L2 cache.
EPFHIT	Prefetch hint hits in the L2 cache.
EPFRCVDS0	Prefetch hint received by slave port S0.
EPFRCVDS1	Prefetch hint received by slave port S1.
IPFALLOC	Allocation of a prefetch generated by L2 cache controller into the L2 cache.
IRHIT	Instruction read hit in the L2 cache.
IRREQ	Instruction read lookup to the L2 cache. Subsequently results in a hit or miss.
SPNIDEN	Secure privileged non-invasive debug enable.
SRCONFS0	Speculative read confirmed in slave port S0.
continued...	

Event	Description
SRCONFS1	Speculative read confirmed in slave port S1.
SRRCVDS0	Speculative read received by slave port S0.
SRRCVDS1	Speculative read received by slave port S1.
WA	Allocation into the L2 cache caused by a write (with write-allocate attribute) miss.

In addition, the L2 cache events can be captured and timestamped using dedicated debugging circuitry.

Related Information

Arm Infocenter

For more information about L2 event capture, refer to the *Debug* chapter of the Cortex-A9 MPCore Technical Reference Manual, available on the ARM Infocenter website.

10.4.1.6. L2 Cache Address Filtering

The L2 cache can access either the system interconnect fabric or the SDRAM L3 interconnect. The L2 cache address filtering determines how much address space is allocated to the HPS-to-FPGA bridge and how much is allocated to SDRAM, depending on the configuration of the memory management unit.

Related Information

- [Cortex-A9 MPU Subsystem with System Interconnect](#) on page 1023
- [Memory Management Unit](#) on page 1030
Information about how the address space is set based on L2 cache address filtering.

10.4.1.7. Cache Latency

Latency for cache hits and misses varies.

The latency for an L1 cache hit is 1 clock. The latency for an L1 cache miss and L2 cache hit is 6 clocks best case. Latency in the L2 cache can vary depending on other operations in the L2. Parity and ECC settings have no effect on latency. A single-bit ECC error is corrected during the L2 read, but is not re-written to the L2 RAM.

10.5. CPU Prefetch

The Cortex-A9 performs instruction and data prefetches regardless of the state of the MMU.

A prefetch occurs when any address that is 4 KB above the current instruction pointer is accessed. The system has been designed to ensure that the system bus does not lock on prefetches. Any prefetches to unmapped memory space produce a decode error on the system interconnect.

10.6. TrustZone

As platforms allow more outside application downloads and as sensitive data is shared on devices, risks of hardware or data asset attacks rise. The Cortex-A9 MPU subsystem has integrated TrustZone technology which provides a system solution to protect application platforms from malicious attack. The TrustZone hardware and supporting software are designed to provide a strong security solution regardless of the operating environment. TrustZone creates a separation between the secure and non-secure areas of the SoC and allows the designer to choose which assets in a design are designated as secure and non-secure.

TrustZone security is implemented in the Cortex-A9 MPU subsystem in three ways:

- Hardware partitioning: Resources can be assigned and identified as secure or non-secure.
- Virtual processor execution: Each core can context switch between secure and non-secure operation.
- Secure debug control: The MPU subsystem provides both secure and non-secure hardware debug features. The type of debug allowed can be configured by the user.

Related Information

TrustZone

For more information about the use of the TrustZone, refer to the *Cortex-A9 MPCore Technical Reference Manual*, available on the ARM Infocenter website.

10.6.1. Secure Partitioning

System interconnect and cache accesses as well as processor execution can be securely partitioned using the TrustZone infrastructure.

10.6.1.1. Secure Bus Accesses

The Cortex-A9 MPCore and other masters that utilize the system interconnect can be configured for secure or non-secure accesses.

Master accesses drive a protection signal, `AxPROT[1]`, to communicate the security level of the attempted transaction. The Cortex-A9 drives this signal low for secure accesses and high for non-secure accesses. The secure firewalls determine whether the access is allowed or not. A slave access type defaults to secure if no other configuration is programmed. Users can define whether a bus error is generated or if a bus failure occurs when a secure access is violated.

Note: Secure processor configuration is programmed through the CP15 register.

Related Information

- [Arria 10 HPS Secure Firewalls](#) on page 353
For more detailed information about secure bus accesses, refer to the "Secure Firewall" section.
- [SoC Security](#) on page 332
For more information about SoC Security, refer to the *SoC Security* Chapter.

10.6.1.2. Secure Cache Accesses

Secure and non-secure partitioning also extends to the L1 and L2 caches.

There is a 32-bit physical address space for secure and non-secure transactions and a 33rd bit is provided to indicate security. The cache is able to store both secure and non-secure lines.

The Accelerator Coherency Port (ACP) in the ArmCortex-A9 MPCore can be used with TrustZone technology. The security state of the masters using the ACP must be the same as the Cortex-A9 processor.

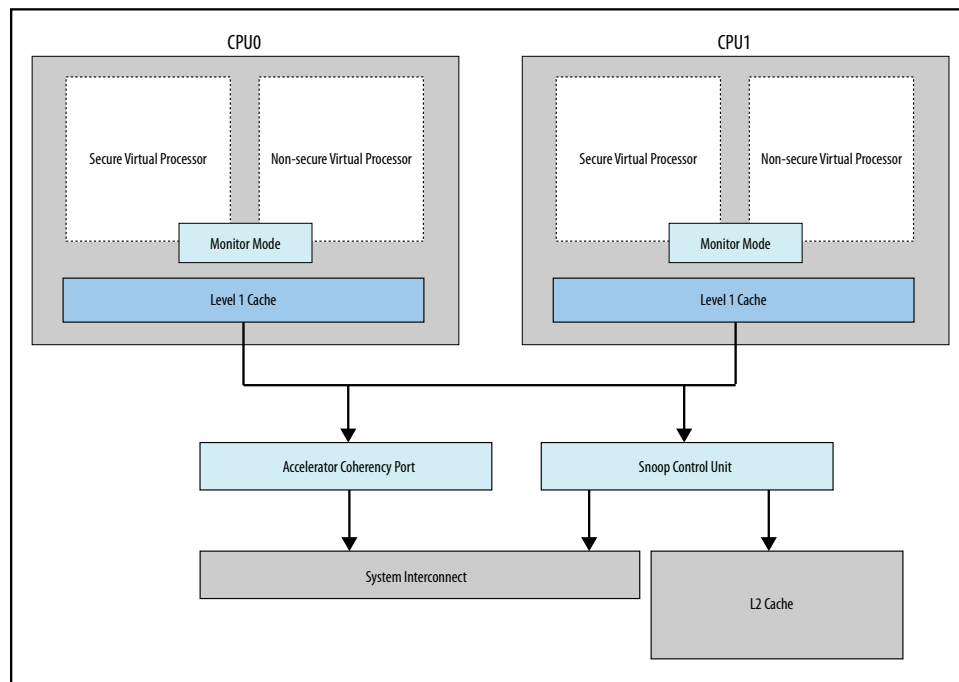

Related Information

- [ARM TrustZone](#)
Refer to this location for information about virtual core operation.
- [SoC Security](#) on page 332
For more information about SoC Security, refer to the *SoC Security* Chapter.

10.6.2. Virtual Processor Operation

Two virtual processors (secure and non-secure) with context switch capability (monitor mode) exist for each Cortex-A9 processor core. The secure virtual processor only accesses secure resources and the non-secure virtual processor only accesses non-secure resources.

Figure 43. Virtual Processor Environment with Monitor Mode

A context switch to secure operation is achieved through a secure monitor call (SMC) instruction or the following hardware exceptions (if configured to do so):

- IRQ interrupt
- Faster Interrupt Request (FIQ) interrupt
- External data abort
- External prefetch abort

When a context switch occurs, the state of the current mode is saved and restored on the next context switch or on a return from exception.

Exception Vector Tables

Three exception vector tables are provided for the MPU with TrustZone:

1. Non-secure
2. Secure
3. Monitor mode

Typically IRQs are used for non-secure interrupts and FIQs are used for secure interrupts. The location of each of the three vector tables can be moved at runtime.

The Generic Interrupt Controller (GIC) can handle secure and non-secure interrupts and prevent non-secure accesses from reading or modifying the configuration of a secure interrupt. An interrupt can be made secure by programming the appropriate bits in the Interrupt Security Register. Secure interrupts are always given a higher priority than non-secure interrupts.

10.6.3. Secure Debug

Debug security extensions exist for the MPU subsystem and the system SoC. Secure privileged and user processor debug access can be controlled by two input pins to the core logic. Depending on the configuration of these pins, secure privileged or user JTAG or trace can be used. In addition, normal user debug visibility can be allowed while preventing all secure world debug. To disable all visibility to the core, both secure and non-secure, a global debug pin, `NIDEN`, is provided to the core. Each Cortex-A9 processor in an MPU subsystem has its own dedicated debug visibility signals.

Related Information

[CoreSight Debug and Trace](#) on page 1064

10.7. Debugging Modules

The MPU subsystem includes debugging resources through Arm CoreSight on-chip debugging and trace. The following functionality is included:

- Individual program trace for each processor
- Event trace for the Cortex-A9 MPCore
- Cross triggering between processors and other HPS debugging features

10.7.1. Program Trace

Each processor has an independent program trace monitor (PTM) that provides real-time instruction flow trace. The PTM is compatible with a number of third-party debugging tools.

The PTM provides trace data in a highly compressed format. The trace data includes tags for specific points in the program execution flow, called waypoints. Waypoints are specific events or changes in the program flow.

The PTM recognizes and tags the waypoints listed in [Table 120](#) on page 1058.

Table 120. Waypoints Supported by the PTM

Type	Additional Waypoint Information
Indirect branches	Target address and condition code
Direct branches	Condition code
Instruction barrier instructions	—
Exceptions	Location where the exception occurred
Changes in processor instruction set state	—
Changes in processor security state	—
Context ID changes	—
Entry to and return from debug state when Halting debug mode is enabled	—

The PTM optionally provides additional information for waypoints, including the following:

- Processor cycle count between waypoints
- Global timestamp values
- Target addresses for direct branches

Related Information

- [CoreSight Debug and Trace](#) on page 1064
- [Arm Infocenter](#)
For more information about the PTM, refer to the CoreSight PTM-A9 Technical Reference Manual, available on the ARM Infocenter website.

10.7.2. Event Trace

Events from each processor can be used as inputs to the PTM. The PTM can use these events as trace and trigger conditions.

Related Information

- [Performance Monitoring Unit](#) on page 1033
- [Arm Infocenter](#)
For more information about the trigger and trace capabilities, refer to the CoreSight PTM-A9 Technical Reference Manual, Revision r1p0, available on the ARM Infocenter website.

10.7.3. Cross-Triggering

The PTM can export trigger events and perform actions on trigger inputs. The cross-trigger signals interface with other HPS debugging components including the FPGA fabric. Also, a breakpoint in one processor can trigger a break in the other.

Related Information

[CoreSight Debug and Trace](#) on page 1064

For detailed information about cross-triggering and about debugging hardware in the MPU, refer to the *CoreSight Debug and Trace* chapter.

10.8. Clocks

Three synchronous clocks and two debug clocks are provided to the MPU subsystem.

Table 121. MPU Subsystem Clocks

System Clock Name	Use
mpu_clk	Main clock for the MPU subsystem
mpu_periph_clk	Clock for peripherals inside the MPU subsystem
mpu_l2_ram_clk	Clock for L2 cache and AXI interface clocks to and from the system interconnect
dbg_at_clk	Trace bus clock
dbg_clk	Debug clock

Related Information

[Clock Manager](#) on page 56

10.9. Cortex-A9 MPU Subsystem Register Implementation

The following configurations are available through registers in the Cortex-A9 subsystem:

- All processor-related controls, including the MMU and L1 caches, are controlled using the Coprocessor 15 (CP15) registers of each individual processor.
- All SCU registers, including control for the timers and GIC, are memory mapped.
- All L2 cache registers are memory-mapped.

Related Information

[Arm Infocenter](#)

For detailed definitions of the registers for the Cortex-A9 MPU subsystem, refer to the Cortex-A9 MPCore Technical Reference Manual, Revision r4p1 and the CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual, Revision r3p3, available on the ARM Infocenter website.

10.9.1. Cortex-A9 MPU Subsystem Address Map for Arria 10

The Cortex-A9 MPU subsystem registers reside within the address range from 0xFFFFC000 to 0xFFFFEFFF.

10.9.1.1. mpu_regs_MPUSCU Address Map

This address space is allocated for the Snoop Control Unit (SCU) registers. For detailed information about the use of this address space, go to the [ARM Infocenter](#) to access the ARM* documentation for the Cortex-A9 MPCore.

Module Instance	Base Address	End Address
mpu_regs_MPUSCU	0xFFFFC000	0xFFFFC0FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

10.9.1.2. mpu_regs_MPUGIC Address Map

This address space is allocated for the General Interrupt Controller (GIC) registers. For detailed information about the use of this address space, go to the [ARM Infocenter](#) to access the ARM documentation for the Cortex-A9 MPCore.

Module Instance	Base Address	End Address
mpu_regs_MPUGIC	0xFFFFC100	0xFFFFC1FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

10.9.1.3. mpu_regs_MPUGLOBALTIMER Address Map

This address space is allocated for the Global Timer registers. For detailed information about the use of this address space, go to the [ARM Infocenter](#) to access the ARM documentation for the Cortex-A9 MPCore.

Module Instance	Base Address	End Address
mpu_regs_MPUGLOBALTIMER	0xFFFFC200	0xFFFFC5FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

10.9.1.4. mpu_regs_MPUPRIVATETIMER Address Map

This address space is allocated for the Private Timers and Watchdog registers. For detailed information about the use of this address space, go to the [ARM Infocenter](#) to access the ARM documentation for the Cortex-A9 MPCore.

Module Instance	Base Address	End Address
mpu_regs_MPUPRIVATETIMER	0xFFFFC600	0xFFFFCFFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

10.9.1.5. mpu_regs_MPUINTRDIST Address Map

This address space is allocated for the Interrupt Distributor registers. For detailed information about the use of this address space, go to the [ARM Infocenter](#) to access the ARM documentation for the Cortex-A9 MPCore.

Module Instance	Base Address	End Address
mpu_regs_MPUINTRDIST	0xFFFFD000	0xFFFFEFFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

10.9.2. L2 Cache Controller Address Map for Arria 10

The register space for the L2 cache controller ranges from 0xFFFFF000 to 0xFFFFFFFF

10.9.2.1. l2_regs_L2TYPE Address Map

This address space is allocated for the Cache ID and Cache Type registers. For detailed information about the use of this address space, go to the [ARM Infocenter](#) to access the Arm documentation for the L2C-301.

Module Instance	Base Address	End Address
l2_regs_L2TYPE	0xFFFFF000	0xFFFFF0FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

10.9.2.2. l2_regs_L2CONTROL Address Map

This address space is allocated for the Control registers. For detailed information about the use of this address space, go to the [ARM Infocenter](#) to access the Arm documentation for the L2C-301.

Module Instance	Base Address	End Address
l2_regs_L2CONTROL	0xFFFFF100	0xFFFFF1FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

10.9.2.3. l2_regs_L2INTERRUPT Address Map

This address space is allocated for the Interrupt and Counter Control registers. For detailed information about the use of this address space, go to the [ARM Infocenter](#) to access the Arm documentation for the L2C-301.

Module Instance	Base Address	End Address
l2_regs_L2INTERRUPT	0xFFFFF200	0xFFFFF6FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

10.9.2.4. l2_regs_L2MAINTENANCE Address Map

This address space is allocated for the Cache Maintenance registers. For detailed information about the use of this address space, go to the [ARM Infocenter](#) to access the Arm documentation for the L2C-301.

Module Instance	Base Address	End Address
l2_regs_L2MAINTENANCE	0xFFFFF700	0xFFFFF8FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

10.9.2.5. l2_regs_L2LOCKDOWN Address Map

This address space is allocated for the Cache Lockdown registers. For detailed information about the use of this address space, go to the [ARM Infocenter](#) to access the Arm documentation for the L2C-301.

Module Instance	Base Address	End Address
l2_regs_L2LOCKDOWN	0xFFFFF900	0xFFFFFBFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

10.9.2.6. l2_regs_L2ADDRESSFILTER Address Map

This address space is allocated for the Address Filtering registers. For detailed information about the use of this address space, go to the [ARM Infocenter](#) to access the Arm documentation for the L2C-301.

Module Instance	Base Address	End Address
l2_regs_L2ADDRESSFILTER	0xFFFFFC00	0xFFFFFEFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

10.9.2.7. l2_regs_L2DEBUG Address Map

This address space is allocated for the Debug, Prefetch and Power registers. For detailed information about the use of this address space, go to the [ARM Infocenter](#) to access the Arm documentation for the L2C-301.

10. Cortex-A9 Microprocessor Unit Subsystem

a10_5v4 | 2017.07.22

Module Instance	Base Address	End Address
l2_regs_L2DEBUG	0xFFFFF00	0xFFFFFFFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

11. CoreSight Debug and Trace

CoreSight systems provide all the infrastructure you require to debug, monitor, and optimize the performance of a complete HPS design. CoreSight technology addresses the requirement for a multicore debug and trace solution with high bandwidth for whole systems beyond the processor core.

CoreSight technology provides the following features:

- Cross-trigger support between SoC subsystems
- High data compression
- Multi-source trace in a single stream
- Standard programming models for standard tool support

The hard processor system (HPS) debug infrastructure provides visibility and control of the HPS modules, the Arm Cortex-A9 microprocessor unit (MPU) subsystem, and user logic implemented in the FPGA fabric. The debug system design incorporates Arm CoreSight components.

Details of the Arm CoreSight debug components can be viewed by clicking on the following related information links:

11.1. Features of CoreSight Debug and Trace

The CoreSight debug and trace system offers the following features:

- Real-time program flow instruction trace through a separate Program Trace Macrocell (PTM) for each processor
- Host debugger JTAG interface
- Connections for cross-trigger and STM-to-FPGA interfaces, which enable soft IP generation of triggers and system trace messages
- External trace interface through Trace Port Interface Unit (TPIU) for trace analysis tools
- Custom message injection through the System Trace Macrocell (STM) into the trace stream for delivery to a host debugger
- STM, PTM, and level 3 (L3) trace sources multiplexed into a single stream through the Trace Funnel
- Capability to route trace data to any slave accessible to the Embedded Trace Router (ETR) AXI master connected to the L3 interconnect
- Capability for the following components to trigger each other through the embedded cross-trigger system:
 - Cortex-A9 PTM-0
 - Cortex-A9 PTM-1
 - STM
 - Embedded Trace FIFO (ETF)
 - ETR
 - TPIU
 - Cross Trigger Interface (CTI)
 - FPGA-CTI
 - Cross Trigger Matrix (CTM)

Related Information

11.3. CoreSight Debug and Trace Block Diagram and System Integration

Figure 44. HPS CoreSight Debug and Trace System Block Diagram

11.4. Functional Description of CoreSight Debug and Trace

11.4.1. Debug Access Port

The Debug Access Port (DAP) provides the necessary ports for a host debugger to connect to and communicate with the HPS through a JTAG interface, which is connected to the FPGA JTAG chain. The JTAG interface provided with the DAP allows a

host debugger to access various modules inside the HPS. Additionally, a debug monitor executing on either processor can access different HPS components by interfacing with the system Advanced Microcontroller Bus Architecture (AMBA) Advanced Peripheral Bus (APB) slave port of the DAP.

The system APB slave port occupies 2 MB of address space in the HPS. Both the JTAG port and system APB port have access to the debug APB master port of the DAP.

A host debugger can access any HPS memory-mapped resource in the system through the DAP system master port. Requests made over the DAP system master port are impacted by reads and writes to peripheral registers.

Note: The HPS JTAG interface does not support boundary scan tests (BST). In order to perform boundary scan testing on HPS I/Os, use the FPGA JTAG pins. This can be performed only when the HPS is powered on and the **HPS_nRST** is de-asserted.

11.4.1.1. JTAG Connection

The SoC device has two JTAG controllers: the FPGA JTAG (located in the configuration sub-system (CSS)) and the HPS JTAG (located in the HPS). The controllers have separate instruction sets and work independently. To share the same external JTAG port between the two controllers, they are internally daisy-chained, where the FPGA appears before the HPS on the chain.

The following figure shows how the two test access port (TAP) controllers are connected:

The STM also provides 32 hardware EVENT pins. The higher-order 28 pins (31:4) are connected to the FPGA fabric, allowing logic inside FPGA to insert messages into the trace stream. When the STM detects a rising edge on an EVENT pin, a message identifying the EVENT is inserted into the stream. The lower four EVENT pins (3:0) are connected to CTI.

11.4.4. CoreSight Trace Memory Controller

The CoreSight Trace Memory Controller (TMC) has three possible configurations:

- Embedded Trace FIFO (ETF)
- Embedded Trace Router (ETR)
- Embedded Trace Buffer (ETB)

ETB is not used in this device.

Related Information

[ARM Infocenter](#)

For more information, refer to the *CoreSight System Trace Memory Controller Technical Reference Manual* on the ARM Infocenter website.

11.4.4.1. Embedded Trace FIFO

The Trace Funnel output is sent to the ETF. The ETF is used as an elastic buffer between trace generators (STM, PTM, L3 interconnect) and trace destinations. The ETF stores up to 32 KB of trace data in the on-chip trace RAM.

Related Information

[ARM Infocenter](#)

For more information, refer to the *CoreSight System Trace Memory Controller Technical Reference Manual* on the ARM Infocenter website.

11.4.4.2. Embedded Trace Router

The ETR can route trace data to the HPS on-chip RAM, the HPS SDRAM, and any memory in the FPGA fabric connected to the HPS-to-FPGA bridge. The ETR receives trace data from the AMBA Trace Bus Replicator. By default, the buffer to receive the trace data resides in SDRAM at offset 0x00100000 and is 32 KB. You can override this default configuration by programming registers in the ETR.

Related Information

- [HPS-FPGA Bridges](#) on page 1007
- [CoreSight Debug and Trace Programming Model](#) on page 1079
- [ARM Infocenter](#)
For more information, refer to the *CoreSight System Trace Memory Controller Technical Reference Manual* on the ARM Infocenter website.

11.4.5. AMBA Trace Bus Replicator

The AMBA Trace Bus Replicator broadcasts trace data from the ETF to the ETR and TPIU.

Related Information

[ARM Infocenter](#)
Refer to the *CoreSight Components Technical Reference Manual* on the ARM Infocenter website.

11.4.6. Trace Port Interface Unit

The TPIU is a bridge between on-chip trace sources and an off-chip trace port. The TPIU receives trace data from the Trace Bus Replicator (Replicator) and drives the trace data to a trace port analyzer.

The trace output is routed to a 32-bit interface to the FPGA fabric. The trace data sent to the FPGA fabric can be transported off-chip using available serializer/deserializer (SERDES) resources in the FPGA.

Related Information

[ARM Infocenter](#)
Refer to the *CoreSight Components Technical Reference Manual* on the ARM Infocenter website.

11.4.7. Embedded Cross Trigger System

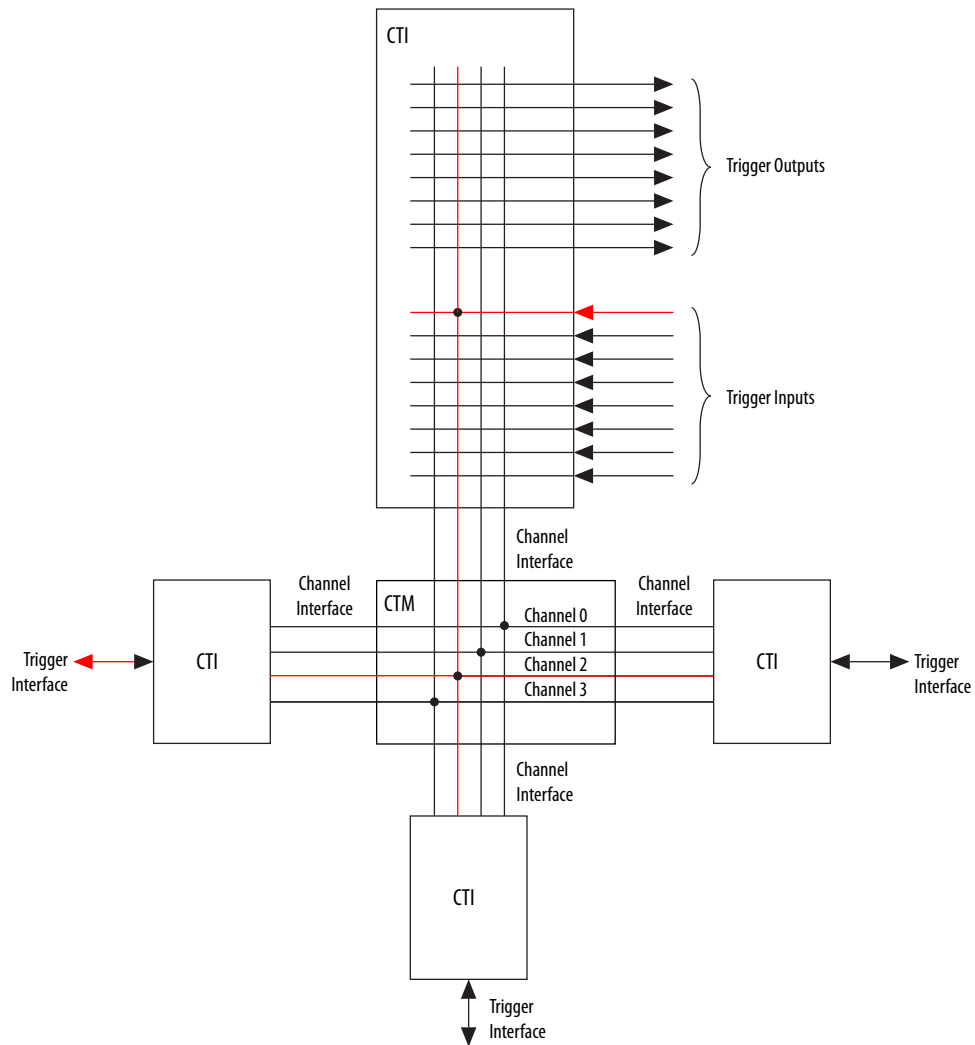

The ECT system provides a mechanism for the components listed in "Features of the CoreSight Debug and Trace" to trigger each other. The ECT consists of the following modules:

- Cross Trigger Interface (CTI)
- Cross Trigger Matrix (CTM)

Figure 45. Generic ECT System

The following figure shows an example of how CTIs and CTMs are used in a generic ECT setup. Though the signal travels through channel 2, it only enters and exits through trigger inputs and outputs you configure.

Note: The red line depicts an trigger input to one CTI generating a trigger output in another CTI.

Related Information

- [Cross Trigger Interface](#) on page 1072
- [Features of CoreSight Debug and Trace](#) on page 1065
- [Cross Trigger Matrix](#) on page 1072

11.4.7.1. Cross Trigger Interface

CTIs allow trigger sources and sinks to interface with the ECT. Each CTI supports up to eight trigger inputs and eight trigger outputs, and is connected to a CTM. [Figure 46](#) on page 1072 shows the relationship of trigger inputs, trigger outputs, and CTM channels of a CTI.

Figure 46. CTI Connections

The following figure shows the eight potential trigger input and trigger output connections that are supported.

The HPS debug system contains the following CTIs:

- CTI—performs cross triggering between the STM, ETF, ETR, and TPIU.
- FPGA-CTI—exposes the cross-triggering system to the FPGA fabric.
- CTI-0 and CTI-1—reside in the MPU debug subsystem. Each CTI is associated with a processor and the processor's PTM.
- L3-CTI—allows cross triggering with L3 interconnect.

11.4.7.2. Cross Trigger Matrix

A CTM is a transport mechanism for triggers traveling from one CTI to one or more CTIs or CTMs. The HPS contains two CTMs. One CTM connects CTI and FPGA-CTI; the other connects CTI-0 and CTI-1. The two CTMs are connected together, allowing triggers to be transmitted between the MPU debug subsystem, the debug system, and the FPGA fabric.

Each CTM has four ports and each port has four channels. Each CTM port can be connected to a CTI or another CTM.

Figure 47. CTM Channel Structure

The following figure shows the structure of a CTM channel. Paths inside the CTM are purely combinatorial.

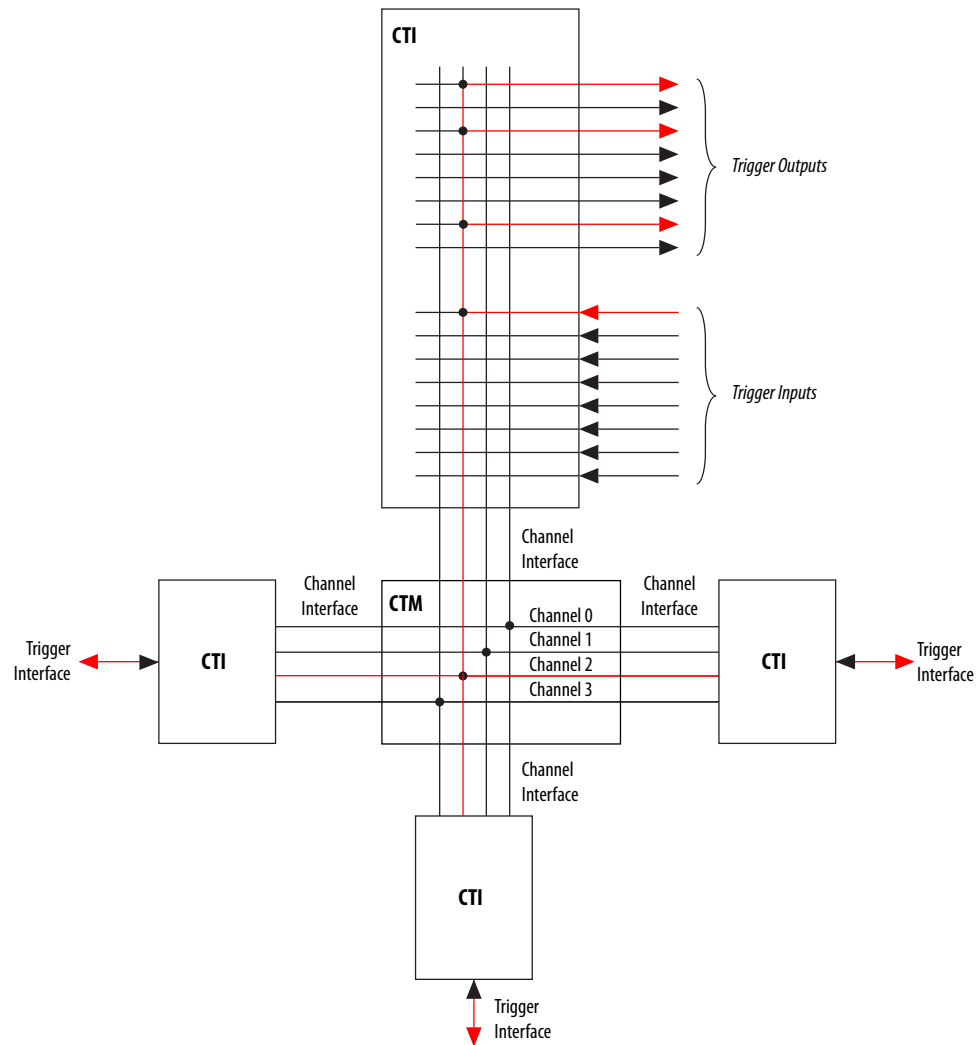

Figure 48. CTI Trigger Connections

Each CTI trigger input can be connected through a CTM to one or more trigger outputs under control by a debugger. The following figure shows an example of CTI trigger connections.

Note: The red lines depict the impact one trigger input can have on the entire system.

Related Information

[ARM Infocenter](#)

Refer to the *CoreSight Components Technical Reference Manual* on the ARM Infocenter website.

11.4.8. Program Trace Macrocell

The PTM performs real-time program flow instruction tracing and provides a variety of filters and triggers that can be used to trace specific portions of code.

The HPS contains two PTMs. Each PTM is paired with a processor and CTI. Trace data generated from the PTM can be transmitted off-chip using HPS pins, or to the FPGA fabric, where it can be pre-processed and transmitted off-chip using high-speed FPGA pins.

Related Information

ARM Infocenter

For more information, refer to the *CoreSight PTM-A9 Technical Reference Manual*.

11.4.9. HPS Debug APB Interface

The HPS can extend the CoreSight debug control bus into the FPGA fabric. The debug interface is an APB-compatible interface with built-in clock crossing.

Related Information

- [FPGA Interface](#) on page 1075
- [HPS Component Interfaces](#) on page 4594

11.4.10. FPGA Interface

The following components connect to the FPGA fabric. This section lists the signals from the debug system to the FPGA.

11.4.10.1. DAP

The DAP uses the system APB port to connect to the FPGA.

Table 123. DAP

The following table shows the signal description between DAP and FPGA.

Signal	Description
h2f_dbg_apb_PADDR	Address bus to system APB port, when PADDR
h2f_dbg_apb_PADDR31	Address bus to system APB port, when PADDR31
h2f_dbg_apb_PENABLE	Enable signal from system APB port
h2f_dbg_apb_PRDATA[32]	32-bit system APB port read data bus
h2f_dbg_apb_PREADY	Ready signal to system APB port
h2f_dbg_apb_PSEL	Select signal from system APB port
h2f_dbg_apb_PSLVERR	Error signal to system APB port
h2f_dbg_apb_PWDATA[32]	32-bit system APB port write data bus
h2f_dbg_apb_PWRITE	Select whether read or write to system APB port <ul style="list-style-type: none"> • 0 - System APB port read from DAP • 1 - System APB Port write to DAP

11.4.10.2. STM

The STM has 28 event pins, `f2h_stm_hw_events[28]`, for FPGA to trigger events to STM.

11.4.10.3. FPGA-CTI

The FPGA-CTI allows the FPGA to send and receive triggers from the debug system.

Table 124. FPGA-CTI Signal Description Table

The following table lists the signal descriptions between the FPGA-CTI and FPGA.

Signal	Description
h2f_cti_trig_in[8]	Trigger input from FPGA
h2f_cti_trig_in_ack[8]	ACK signal to FPGA
h2f_cti_trig_out[8]	Trigger output to FPGA
h2f_cti_trig_out_ack[8]	ACK signal from FPGA
h2f_cti_clk	Clock input from FPGA
h2f_cti_fpga_clk_en	Clock enable driven by FPGA

Related Information

[ARM Infocenter](#)

For more information about the cross-trigger interface

11.4.10.4. CTI-NoC

The CTI is used for receiving triggers from device that can generate triggers and for sending triggers to devices that can receive triggers. This instance of CTI is used exclusively by NoC and allows NoC probe units to send and receive triggers.

Table 125. Trigger Input Interface

Name	Input/Output	Description
CTITRIGIN	Input	Trigger In Connected to noc_CTITRIGIN
TISBYPASSIN	Input	8'b0000_0000 —Trigger In synchronization bypass (Static value) Enable synchronizers for all 8 inputs. CTI runs off cs_at_clk
CTITRIGINACK	Output	Trigger In acknowledge Connected to noc_CTITRIGINACK

Table 126. Trigger Output Interface

Name	Input/Output	Description
CTITRIGOUT	Output	Trigger Out Connected to noc_CTITRIGOUT
CTITRIGOUTACK	Input	Trigger Out acknowledge Connected to noc_CTITRIGOUTACK
TISBYPASSACK	Input	8'b0000_0000—Trigger Out acknowledge synchronization bypass (Static value) Enable synchronizers for all 8 inputs
TIHSBYPASS	Input	8'b0000_0000—Trigger interface handshake bypass (Static value) Hand shaking is enabled

Port Name	Clock Source	Signal Name	Description
CTMCLK (for csCTM)	Clock manager	cs_pdbg_clk	Cross trigger matrix clock for csCTM. It can be synchronous or asynchronous to CTICKL.
CTMCLK (for CTM)	Clock manager	mpu_clk	Cross trigger matrix clock for CTM. It can be synchronous or asynchronous to CTICKL.
DAPCLK	Clock manager	cs_pdbg_clk	DAP internal clock. It must be equivalent to PCLKDBG.
PCLKDBG	Clock manager	cs_pdbg_clk	Debug APB (DAPB) clock.
HCLK	Clock manager	cs_pdbg_clk	Used by the AHB-Lite master inside the DAP. It is asynchronous to DAPCLK. In the HPS, the AHB-Lite port uses same clock as DAPCLK.
PCLKSYS	Clock manager	cs_pdbg_clk	Used by the APB slave port inside the DAP. It is asynchronous to DAPCLK.
SWCLKTCK	JTAG interface	dap_tck	The SWJ-DP clock driven by the external debugger through the JTAG interface. It is asynchronous to DAPCLK. When through the JTAG interface, this clock is the same as TCK of the JTAG interface.
TRACECLKIN	Clock manager	cs_trace_clk	TPIU trace clock input. It is asynchronous to ATCLK. In the HPS, this clock can come from the clock manager or the FPGA fabric.

Related Information

ARM Infocenter

For more information about the CoreSight port names, refer to the *CoreSight Technology System Design Guide*.

11.4.12. Debug Resets

The CoreSight system uses several resets.

Table 129. CoreSight Resets

Arm Reset Name	Clock Source	HPS Reset Signal Name	Description
ATRESETn	Reset manager	dbg_rst_n	Trace bus reset. It resets all registers in the ATCLK domain.
nCTIRESET	Reset manager	dbg_rst_n	CTI reset signal. It resets all registers in the CTICKL domain. In the HPS, there are four instances of CTI. All four use the same reset signal.
DAPRESETn	Reset manager	dbg_rst_n	DAP internal reset. It is connected to PRESETDBGn.
continued...			

Arm Reset Name	Clock Source	HPS Reset Signal Name	Description
PRESETDBGn	Reset manager	dbg_rst_n	Debug APB reset. Resets all registers clocked by PCLKDBG.
HRESETn	Reset manager	sys_dbg_rst_n	SoC-provided reset signal that resets all of the AMBA on-chip interconnect. Use this signal to reset the DAP AHB-Lite master port.
PRESETSYSn	Reset manager	sys_dbg_rst_n	Resets system APB slave port of DAP.
nCTMRESET	Reset manager	dbg_rst_n	CTM reset signal. It resets all signals clocked by CTMCLK.
nPOTRST	Reset manager	tap_cold_rst_n	True power on reset signal to the DAP SWJ-DP. It must only reset at power-on.
nTRST	JTAG interface	nTRST pin	Resets the DAP TAP controller inside the SWJ-DP. This signal is driven by the host using the JTAG connector.
TRESETn	Reset manager	dbg_rst_n	Reset signal for TPIU. Resets all registers in the TRACECLKIN domain.

The ETR stall enable field (`etrstallen`) of the `ctrl` register in the reset manager controls whether the ETR is requested to stall its AXI master interface to the L3 interconnect before a warm or debug reset.

The level 4 (L4) watchdog timers can be paused during debugging to prevent reset while the processor is stopped at a breakpoint.

11.5. CoreSight Debug and Trace Programming Model

This section describes programming model details specific to the device implementation of the Arm CoreSight technology.

The debug components can be configured to cause triggers when certain events occur. For example, soft logic in the FPGA fabric can signal an event which triggers an STM message injection into the trace stream.

Related Information

[ARM Infocenter](#)

Programming interface details of each CoreSight component.

11.5.1. Coresight Component Address

CoreSight components are configured through memory-mapped registers, located at offsets relative to the CoreSight component base address. CoreSight component base addresses are accessible through the component address table in the DAP ROM.

Table 130. Coresight Component Address Table

The following table is located in the ROM table portion of the DAP.

ROM Entry	Offset[30:12]	Description
0x0	0x00001	ETF Component Base Address
0x1	0x00002	CTI Component Base Address
0x2	0x00003	TPIU Component Base Address
0x3	0x00004	Trace Funnel Component Base Address
0x4	0x00005	STM Component Base Address
0x5	0x00006	ETR Component Base Address
0x6	0x00007	FPGA-CTI Component Base Address
0x7	0x00100	A9 ROM
0x8	0x00080	FPGA ROM
0x9	0x00008	L3-CTI

A host debugger can access this table at 0x80000000 through the DAP. HPS masters can access this ROM at 0xFF000000. Registers for a particular CoreSight component are accessed by adding the register offset to the CoreSight component base address, and adding that total to the base address of the ROM table.

The base address of the ROM table is different when accessed from the debugger (at 0x8000_0000) than when accessed from any HPS master (at 0xFF000000). For example, the CTI output enable (CTIOUTEN) register, CTIOUTEN[2] at offset 0xA8, can be accessed by the host debugger at 0x800020A8. To derive that value, add the host debugger access address to the ROM table of 0x80000000, to the CTI component base address of 0x00002000, to the CTIOUTEN[2] register offset of 0xA8.

11.5.2. STM Channels

The STM AXI slave is connected to the MPU, DMA, and FPGA-to-HPS bridge masters. Each master has up to 65536 channels where each channel occupies 256 bytes of address space, for a total of 16 MB per master. The HPS address map allocates 48 MB of consecutive address space to the STM AXI slave port, divided in three 16 MB segments.

Table 131. STM AXI Slave Port Address Allocation

Segment	Start Address	End Address
0	0xFC000000	0xFCFFFFFF
1	0xFD000000	0xFDFFFFFF
2	0xFE000000	0xFEFFFFFF

Each of the three masters can access any one of the three address segments. Your software design determines which master uses which segment, based on the value of bits 24 and 25 in the write address, AWADDRS[25:24]. Software must restrict each master to use only one of the three segments.

Table 132. STM AXI Address Fields

STM receives trace data over an AXI slave port. This table contains a list of signals associated with this interface.

AXI Signal Fields	Description
AWADDRS[7:0]	These bits index the 256 bytes of the stimulus port.
AWADDRS[23:8]	These bits identify the 65536 stimulus ports associated with a master.
AWADDRS[25:24]	These bits identify the three masters. Only 0, 1, and 2 are valid values.
AWADDRS[31:26]	Always 0x3F. Bits 24 to 31 combine to access 0xFC000000 through 0xFEFFFFFF.

Each STM message contains a master ID that tells the host debugger which master is associated with the message. The STM master ID is determined by combining a portion of the AWADDRS signal and the AWPROT protection bit. In the following table, MasterID[6] identifies the

Table 133. STM Master ID Calculation

Master ID Bits	AXI Signal Bits	Notes
Master ID[5:0]	AWADDRS[29:24]	The lowest two bits are sufficient to determine which master, but CoreSight uses a six-bit master ID.
Master ID[6]	AWPROT[1]	0 indicates a secure master; 1 indicates a nonsecure master.

In addition to access through STM channels, the higher-order 28 (31:4) of the 32 event signals are attached to the FPGA through the FPGA-CTI. These event signals allow the FPGA fabric to send additional messages using the STM.

11.5.3. CTI Trigger Connections to Outside the Debug System

The following CTIs in the HPS debug system connect to outside the debug system:

- CTI
- FPGA-CTI
- L3-CTI

11.5.3.1. CTI

This section lists the trigger input, output, and output acknowledge pin connections implemented for CTI in the debug system. The trigger input acknowledge signals are not connected to pins.

Table 134. CTI Trigger Input Signals

The following table lists the trigger input pin connections implemented for CTI .

Number	Signal	Source
7	ASYNOUT	STM
6	TRIGOUTHETE	STM
5	TRIGOUTSW	STM
4	TRIGOUTSPTE	STM
3	ACQCOMP	ETR
2	FULL	ETR
1	ACQCOMP	ETF
0	FULL	ETF

Table 135. CTI Trigger Output Signals

The following table lists the trigger output pin connections implemented for CTI .

Number	Signal	Destination
7	TRIGIN	ETF
6	FLUSHIN	ETF
5	HWEVENTS[3:2]	STM
4	HWEVENTS[1:0]	STM
3	TRIGIN	TPIU
2	FLUSHIN	TPIU
1	TRIGIN	ETR
0	FLUSHIN	ETR

Table 136. CTI Trigger Output Acknowledge Signals

The following table lists the trigger output pin acknowledge connections implemented for CTI .

Number	Signal	Source
7	0	—
6	0	—
5	0	—
4	0	—
3	TRIGINACK	TPIU
2	FLUSHINACK	TPIU
1	0	—
0	0	—

11.5.3.2. FPGA-CTI

FPGA-CTI connects the debug system to the FPGA fabric. FPGA-CTI has all of its triggers available to the FPGA fabric.

Related Information

[Configuring Embedded Cross-Trigger Connections](#) on page 1083

For more information about the triggers, refer to the "Configuring Embedded Cross-Trigger Connections" chapter.

11.5.3.3. L3-CTI

L3-CTI has all of its triggers available to the L3 interconnect.

11.5.4. Configuring Embedded Cross-Trigger Connections

CTI interfaces are programmable through a memory-mapped register interface.

The specific registers are described in the *CoreSight Components Technical Reference Manual*, which you can download from the Arm Infocenter.

To access registers in any CoreSight component through the debugger, the register offsets must be added to the CoreSight component's base address. That combined value must then be added to the address at which the ROM table is visible to the debugger (0x80000000).

Each CTI has two interfaces, the trigger interface and the channel interface. The trigger interface is the interface between the CTI and other components. It has eight trigger signals, which are hardwired to other components. The channel interface is the interface between a CTI and its CTM, with four bidirectional channels. The mapping of trigger interface to channel interface (and vice versa) in a CTI is dynamically configured. You can enable or disable each CTI trigger output and CTI trigger input connection individually.

For example, you can configure trigger input 0 in the FPGA-CTI to route to channel 3, and configure trigger output 3 in the FPGA-CTI and trigger output 7 in CTI-0 in the MPU debug subsystem to route from channel 3. This configuration causes a trigger at trigger input 0 in FPGA-CTI to propagate to trigger output 3 in the FPGA-CTI and trigger output 7 in CTI-0. Propagation can be single-to-single, single-to-multiple, multiple-to-single, and multiple-to-multiple.

A particular soft logic signal in the FPGA connected to a trigger input in the FPGA-CTI can be configured to trigger a flush of trace data to the TPIU. For example, you can configure channel 0 to trigger output 2 in the CTI. Then configure trigger input T3 to channel 0 in FPGA-CTI. Trace data is flushed to the TPIU when a trigger is received at trigger output 2 in the CTI.

Another soft logic signal in the FPGA connected to trigger input T2 in the FPGA-CTI can be configured to trigger a STM message. The CTI output triggers 4 and 5 are wired to the STM CoreSight component in the HPS. For example, configure channel 1 to trigger output 4 in the CTI; and then configure trigger input T2 to channel 1 in FPGA-CTI.

Another soft logic signal in the FPGA fabric connected to trigger input T1 in FPGA-CTI can be configured to trigger a breakpoint on CPU 1. Trigger output 1 in CTI-1 is wired to the debug request (EDBGRQ) signal of CPU-1. For example, configure channel 2 to trigger output 1 in CTI-1. Then configure trigger input T1 to channel 2 in FPGA-CTI.

Related Information

- [Coresight Component Address](#) on page 1079

- [ARM Infocenter](#)
For more information about the cross-trigger interface

11.5.4.1. Configuring Trigger Input 0

For example, you can configure trigger input 0 in the FPGA-CTI to route to channel 3, and configure trigger output 3 in the FPGA-CTI and trigger output 7 in CTI-0 in the MPU debug subsystem to route from channel 3. This configuration causes a trigger at trigger input 0 in FPGA-CTI to propagate to trigger output 3 in the FPGA-CTI and trigger output 7 in CTI-0. Propagation can be single-to-single, single-to-multiple, multiple-to-single, and multiple-to-multiple.

11.5.4.2. Triggering a Flush of Trace Data to the TPIU

A particular soft logic signal in the FPGA connected to a trigger input in the FPGA-CTI can be configured to trigger a flush of trace data to the TPIU. For example, you can configure channel 0 to trigger output 2 in CTI. Then configure trigger input T3 to channel 0 in FPGA-CTI. Trace data is flushed to the TPIU when a trigger is received at trigger output 2 in CTI.

11.5.4.3. Triggering an STM message

Another soft logic signal in the FPGA connected to trigger input T2 in FPGA-CTI can be configured to trigger an STM message. CTI output triggers 4 and 5 are wired to the STM CoreSight component in the HPS. For example, configure channel 1 to trigger output 4 in CTI. Then configure trigger input T2 to channel 1 in FPGA-CTI.

11.5.4.4. Triggering a Breakpoint on CPU 1

Another soft logic signal in the FPGA fabric connected to trigger input T1 in FPGA-CTI can be configured to trigger a breakpoint on CPU 1. Trigger output 1 in CTI-1 is wired to the external debug request (EDBGRQ) signal of CPU-1. For example, configure channel 2 to trigger output 1 in CTI-1. Then configure trigger input T1 to channel 2 in FPGA-CTI.

11.6. CoreSight Debug and Trace Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the [Arria 10 HPS Address Map and Register Definitions](#).

11.6.1. stm Address Map

This address space is allocated for the CoreSight System Trace Macrocell (STM). For more information about the STM, refer to the [ARM Infocenter](#).

Module Instance	Base Address	End Address
i_stm	0xFC000000	0xFEFFFFFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

11.6.2. dap Address Map

This address space is allocated for the Debug Access Port (DAP). For more information about the DAP, refer to the [ARM Infocenter](#).

Module Instance	Base Address	End Address
i_dap	0xFF000000	0xFF1FFFFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

11.6.3. mpu_regs_MPUSCU Address Map

This address space is allocated for the Snoop Control Unit (SCU) registers. For detailed information about the use of this address space, go to the [ARM Infocenter](#) to access the ARM documentation for the Cortex-A9 MPCore.

Module Instance	Base Address	End Address
mpu_regs_MPUSCU	0xFFFFC000	0xFFFFC0FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

11.6.4. l2_regs_L2DEBUG Address Map

This address space is allocated for the Debug, Prefetch and Power registers. For detailed information about the use of this address space, go to the [ARM Infocenter](#) to access the Arm documentation for the L2C-301.

Module Instance	Base Address	End Address
l2_regs_L2DEBUG	0xFFFFFFFF00	0xFFFFFFFFFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

12. Error Checking and Correction Controller

Error Checking and Correction (ECC) controllers provide single- and double-bit error memory protection for integrated on-chip RAM and peripheral RAMs within the hard processor system (HPS).

Related Information

[Intel Arria 10 Hard Processor System Technical Reference Manual Revision History](#) on page 17

For details on the document revision history of this chapter

12.1. ECC Controller Features

The features supported by each ECC controller are:

- Hamming code-based ECC calculations
- Single-bit error detection and correction
- Double-bit error detection
- Dedicated hardware block for memory data initialization
- Indirect memory access for:
 - Data correction on the corrupted memory address
 - Data and ECC syndrome bit error injection
- Watchdog timeout for indirect access to prevent bus stall
- Display of the current single or double-bit error memory address
- Single-bit error occurrence counter
- Look-up table (LUT) for logging single-bit error memory address
- Interrupt generated upon single and double-bit errors
- User-controllable interrupt assertion for test purposes

12.2. ECC Supported Memories

In addition to the 256 KB on-chip RAM, the peripherals that have integrated memories with ECC controllers are:

- USB OTG 0/1
- SD/MMC controller
- Ethernet MAC 0/1/2

- DMA controller
- NAND flash controller
- QSPI flash controller

Note: The L2 cache and the SDRAM interface have their own dedicated ECC support.

Related Information

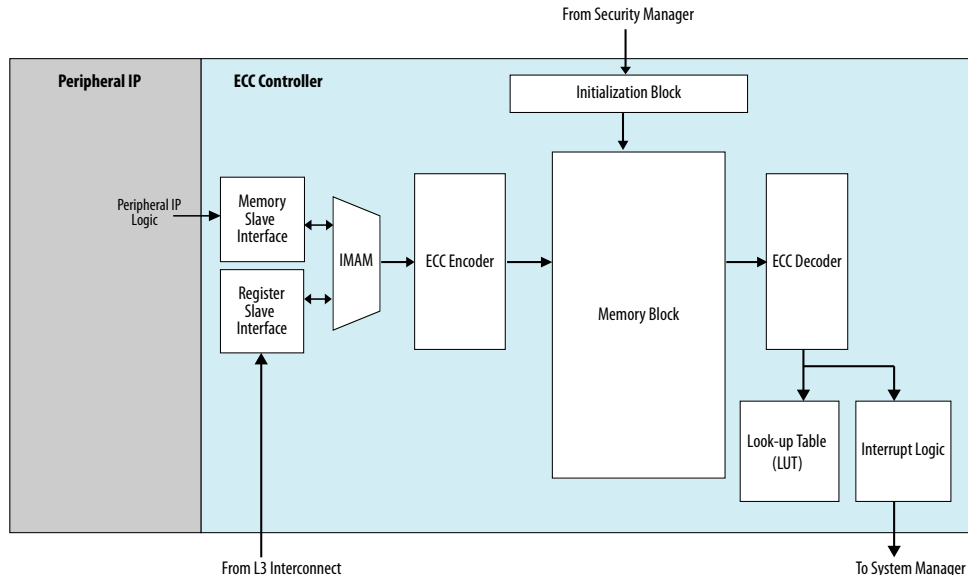

[Cortex-A9 Microprocessor Unit Subsystem](#) on page 1022
For more information regarding L2 Cache ECC support.

12.3. ECC Controller Block Diagram and System Integration

The figure below shows the ECC controller components and the ECC controller communication with other HPS peripherals.

Figure 50. ECC Block Diagram and System Integration

This figure applies to any of the peripheral IP that have ECC-supported memories.

Each peripheral accesses its memory block through the memory slave interface. The register slave interface allows the Microprocessor Unit (MPU) subsystem to access registers in the ECC controller for software configuration of the ECC controller. The register slave interface also allows the MPU subsystem to indirectly access the memory block through the indirect memory access MUX (IMAM).

Before the peripheral writes data to its memory block, it is encoded in the ECC controller. Before memory sends read data to a peripheral, it is decoded by the ECC controller. The initialization block initializes the memory data content, as well as the ECC syndrome bits, to known values. This block is controlled by the register slave interface and also by the Security Manager when memory clearing is required during a tamper event.

When enabled, the look-up table (LUT) records the memory address of all single-bit errors, allowing you to analyze the error rate history.

The interrupt logic provides interrupt capability for single- and double-bit errors.

Related Information

[Indirect Memory Access](#) on page 1091

12.4. ECC Controller Functional Description

12.4.1. Overview

An ECC controller can be enabled or disabled by programming the ECC Control (CTRL) register. The controller is disabled by default when the HPS is released from reset. When the ECC controller is disabled, data written to the memory block is not encoded, and data read from the memory block does not require ECC decoding. When the ECC controller is enabled, single-bit errors can be detected and corrected by the ECC controller. Double-bit errors are detected but not corrected.

12.4.2. ECC Structure

The ECC is calculated based on a Hamming code for the corresponding data word length.

Table 137. ECC Bits Required Based on Data Width

Data Bus Width	ECC Bits
8 to 15 bits	5
16 to 31 bits	6
32 to 63 bits	7
64 to 127 bits	8
128 to 255 bits	9
256 bits	10

**Table 138. ECC Memory Characteristics**

This table shows the memory data size and the Hamming code word length for each of the ECC-protected memories in the HPS, as well as the memory type. The Hamming code word length is calculated based on the full data width and whether the memory is byte- or word- addressable.

Notice that the on-chip RAM and DMA are byte-addressable. For each byte of data, five syndrome bits are used. For a data size of 64 bits (8 bytes), a total of 8 bytes*(8-bit data + 5-bit ECC) bits are used for a Hamming code word.

Peripheral Memory	Data Size	Memory	ECC Bits	Data Width + ECC Bits	Hamming Code Word (length in bits)	Type ⁽²³⁾
On-chip RAM	64 x 32768	Byte-addressable	5 per byte lane	64+40 ⁽²⁴⁾	104	Single port
USB RAM	35 x 8192	Word-addressable	7	35+7	42	Single port
SD/MMC FIFO	32 x 1024	Word-addressable	7	32+7	39	True dual port
EMAC Rx FIFO	35 x 4096	Word-addressable	7	35+7	42	Simple dual port
EMAC Tx FIFO	35 x 1024	Word-addressable	7	35+7	42	Simple dual port
DMA FIFO	64 x 512	Byte-addressable	5 per byte lane	64+40 ⁽²⁴⁾	104	Simple dual port
NAND ECC Buffer	16 x 768	Word-addressable	6	16+6	22	Simple dual port
NAND Write FIFO	32 x 128	Word-addressable	7	32+7	39	Simple dual port
NAND Read FIFO	32 x 32	Word-addressable	7	32+7	39	Simple dual port
QSPI RAM	32 x 128	Word-addressable	7	32+7	39	Single port

12.4.2.1. RAM and ECC Memory Organization Example

The on-chip RAM and DMA have a memory organization that is byte-writeable, where every byte of data requires 5 bits of ECC.

The tables below shows the memory organization of the byte-writable memory with a 64-bit data size and 5 bits of ECC data.

Table 139. Organization of Byte-Writeable Memory with 64-bit Data Size

Address	RAM Bits							
	[63:56]	[55:48]	[47:40]	[39:32]	[31:24]	[23:16]	[15:8]	[7:0]
0x0	data[7]	data[6]	data[5]	data[4]	data[3]	data[2]	data[1]	data[0]
0x8	data[15]	data[14]	data[13]	data[12]	data[11]	data[10]	data[9]	data[8]

⁽²³⁾ True dual-port memory has two writeable and two readable ports. Simple dual port memory has one write-only port and one read-only port.

⁽²⁴⁾ This is the same as 8 byte lanes with 5 ECC bits per lane.

Table 140. Memory Organization of 5-Bit ECC Data

Address	ECC Memory Bits							
	[31:29]	[28:24]	[23:21]	[20:16]	[15:13]	[12:8]	[7:5]	[4:0]
0x0	0x0	ecc_data[3]	0x0	ecc_data[2]	0x0	ecc_data[1]	0x0	ecc_data[0]
0x4	0x0	ecc_data[7]	0x0	ecc_data[6]	0x0	ecc_data[5]	0x0	ecc_data[4]
0x8	0x0	ecc_data[11]	0x0	ecc_data[10]	0x0	ecc_data[9]	0x0	ecc_data[8]
0xC	0x0	ecc_data[15]	0x0	ecc_data[14]	0x0	ecc_data[13]	0x0	ecc_data[12]

12.4.3. Memory Data Initialization

When an ECC controller is enabled, the memory data must be written first before any data read occurs. If the memory is not written, the ECC syndrome bits are random, potentially causing false single- or double-bit errors when the memory data is read.

Every byte of data in the RAM is protected with ECC. This protection can lead to spurious ECC errors under the following conditions:

- When the MPU prefetches any uninitialized locations.
- When the MPU (or any master) reads from an uninitialized byte.

To prevent spurious ECC errors, software must use the memory initialization block in the ECC controller to initialize the entire memory data and ECC bits. The initialization block clears the memory data. Enabling initialization in the ECC Control (CTRL) register is independent of enabling the ECC.

Note: Peripherals with true dual-port memories, such as SD/MMC, must initialize both memories explicitly.

Software controls initialization through the ECC Control (CTRL) register. This process cannot be interrupted or stopped after it starts, therefore software must wait for the initialization complete (INITCOMPLETE*) bit to be set in the Initialization Status (INITSTAT) register. Memory accesses are allowed after the initialization process is complete.

The initialization block is accessed through the register slave interface. Additionally, the Security Manager can access the initialization block. If there is an unauthorized access to the memory or a tamper attempt, the Security Manager signals the Reset Manager to begin scrambling the on-chip memories through the initialization block. After scrambling, the initialization block clears the memory data to zero. This security feature is useful in applications that require secure boot, configuration and authentication.

The Security Manager can also be configured to scramble and clear memory on a cold or warm reset, or both a cold and warm reset. This feature is configured through a combination of user fuses and configuration registers within the Security Manager.

In the Security Manager, you can also select whether the memory is cleared in series or parallel. If time savings is required, memories can be initialized in parallel. If power integrity and savings are required, memories can be initialized in series.

For more information regarding Security Manager functions, refer to the *SoC Security* chapter.

12.4.4. Indirect Memory Access

The register slave interface on an ECC controller allows software to access the memory block indirectly.

Through this interface, software can alter the memory data content and the stored ECC syndrome bits. By directly altering the data and syndrome bits, software can manually correct corrupted data, and run tests and diagnostics on the ECC controller.

Accesses to syndrome bits are not supported by the conventional memory access through the memory slave interface and instead, the ECC encoder handles them automatically.

12.4.4.1. Watchdog Timer

To prevent stalled indirect memory accesses, each ECC controller has a watchdog timer.

For example, if the clock to the memory block is stopped, the watchdog timer can assert an interrupt indicating that memory failed to respond within the expected interval. The watchdog timer is in a separate clock domain from the memory, enabling it to continue running independently of any problem with the memory clock.

The watchdog timer can be enabled or disabled in the ECC Watchdog Control (`ECC_wdctrl`) register. The watchdog timeout is 2048 clock cycles of the clock domain that is connected to the ECC control slave port. The watchdog timeout interval is not software-programmable.

12.4.4.2. Data Correction

The data in the memory block can be overwritten through an indirect memory access. This feature is particularly useful when a double-bit error is detected on the data. The ECC controller provides the memory address of the current double-bit error. The data can be corrected by writing to the given memory address using an indirect memory access.

12.4.4.3. Error Injection

The ECC controller allows you to explicitly inject errors into the memory block for testing purposes. You can alter the memory data or ECC syndrome bits to manually introduce errors. If you change one bit of the memory data to the opposite value, a single-bit error is detected and corrected by the ECC controller. You can also alter ECC syndrome bits to test if the ECC controller triggers an error detection signal as expected.

12.4.4.4. Memory Testing

Testing methods can include both direct and indirect methods of memory access through the peripheral slave interface and the register slave interface. You can use both paths to test the syndrome bits and the single-bit and double-bit error logic. However, you can only control ECC syndrome bits by injecting them through the register slave interface.

12.4.4.4.1. Peripheral Slave Interface Tests

Data and ECC overwrite bits in the `ECC_accctrl` register are provided to test the functionality of the peripheral interface to the ECC-protected RAM.

ECC-Enabled Test

The following sequence can be used to test if the ECC decoder works correctly.

1. Enable the ECC by setting the `ECC_EN` bit in the `CTRL` register.
2. Write data to any ECC-protected RAM memory location. This action generates an ECC value that can be read through the `ECC_Rdataecc0bus` and `ECC_Rdataecc1bus` registers.
3. Read back the memory data. The data read back is expected to match the data originally written (with or without a single-bit error) or generate a double-bit error. Refer to the "Error Logging" section for more details about identifying errors.

ECC-Disabled Test

This sequence can be used to test that the ECC decoder does not produce output when disabled.

1. Disable the ECC by clearing the `ECC_EN` bit in the `CTRL` register.
2. Write to any ECC-protected RAM memory location. No ECC value is expected to be generated and no interrupt or error logging occurs.
3. The ECC value can be read through the `ECC_Rdataecc0bus` and `ECC_Rdataecc1bus` registers to verify that the ECC values do not correspond to the read memory data.

ECC Disable/Enable Test

This sequence shows that memory data written when the ECC controller is disabled generates an error if the ECC controller is subsequently enabled and the same memory data location is read.

1. Disable the ECC by clearing the `ECC_EN` bit in the `CTRL` register.
2. Write to any ECC-protected RAM memory location. No ECC value is expected to be generated and no interrupt or error logging occurs.
3. Enable the ECC by setting the `ECC_EN` bit in the `CTRL` register.
4. Read the data from ECC-protected RAM memory location you wrote in step 2.
5. Expect an error to be generated because the ECC value corresponding to the memory data is not correct. Refer to the "Error Logging" section for more details about identifying errors.

12.4.4.4.2. Register Interface Tests

You can correct memory errors and test the memory register interface through registers in the ECC Controller.

The following registers can be used to test and correct memory:

- `ECC_Addrbus`: Holds the address of the memory and ECC data.
- `ECC_RData3bus` through `ECC_RData0bus`: Holds memory data from a read access.
- `ECC_WData3bus` through `ECC_WData0bus`: Holds the data to be written to memory.
- `ECC_RDataecc1bus` and `ECC_RDataecc0bus`: Holds the ECC data from a read access.
- `ECC_WDataecc1bus` and `ECC_WDataecc0bus`: Holds the ECC data to be written to memory.
- `ECC_accctrl`: Configures the access as a read or a write and enables memory and ECC data overwrites.
- `ECC_startacc`: Initiates the register interface access of memory data or ECC data.

Single-Bit Error Test

This sequence tests the single-bit error detection and correction in the ECC decoder.

1. Enable the ECC by setting the `ECC_EN` bit in the `CTRL` register.
2. Set the Data Override (`DATAOVR`) bit in the `ECC_accctrl` register.
3. Write data to an address location in memory using a normal memory write. Expect the correct ECC data to be generated.
4. Write a data value that has one bit altered in the `ECC_WData3bus` through `ECC_WData0bus` registers and write the address of the memory location in the `ECC_Addrbus`.
5. Configure the `ECC_accctrl` register to a write and set the `ENBUSA` bit of the `ECC_startacc` register to initiate the write. If the memory is dual-ported, an `ENBUSB` bit could optionally be enabled depending on the port access.
6. Read the same memory location using a normal memory read access. Expect a single-bit error to be logged but the data read to be correct. Refer to the "Error Logging" section for more details about identifying errors.

Double-Bit Error Test

This sequence tests the double-bit error detection in the ECC decoder.

1. Enable the ECC by setting the `ECC_EN` bit in the `CTRL` register.
2. Set the Data override (`DATAOVR`) bit in the `ECC_accctrl` register.
3. Write data to an address location in memory using a normal memory write. Expect the correct ECC data to be generated.

4. Write a data value that has two bits altered in the ECC_WData3bus through ECC_WData0bus registers and write the address of the memory location in the ECC_Addrbus.
5. Configure the ECC_accctrl register to a write and set the ENBUSA bit of the ECC_startacc register to initiate the write. If the memory is dual-ported, an ENBUSB bit could optionally be enabled depending on the port access.
6. Read the same memory location using a normal memory read access. Expect a double-bit error to be logged with no data correction. Refer to the "Error Logging" section for more details about identifying errors.

12.4.4.5. Error Checking and Correction Algorithm

The HPS error checking algorithm is based on an extended Hamming code, which is single-error correcting and double-error detecting (SEDED).

The computation can be understood by a given data (d) and a calculation of the check bits (c) through the equation:

$$c = d \times H_d^T$$

where H is the parity check matrix, $H = \{H_d, H_c\}$.

If the code word, designated by v and calculated by:

$$v = \{d, c\}$$

transmits to a noisy channel (for example in a RAM that is subjected to soft errors by cosmic rays) and becomes a contaminated code word, v' , we can recover or discover the errors from its syndrome, s , by using the equation:

$$s = v' \times H^T$$

Errors are indicated when s does not equal 0. The syndrome shows the position of the error in the data.

The following examples show the parity check matrix for different data sizes.

12.4.5. Error Logging

The ECC controller logs the errors that are detected in the memory block. This logging is useful for diagnosing the error and possibly recovering the correct memory data.

12.4.5.1. Recent Error Address Registers

Each ECC controller logs the most recent single-bit and double-bit error memory addresses.

These address values are stored in the ECC Single-Bit Error Address (`SERRADDRx`) and Double-Bit Error Address (`DERRADDRx`) registers and can be read by software. These registers store the most recent memory error address. The logged address is a word address, rather than a byte address value, so that software must shift the address left to obtain the true address corresponding to the address width. For example, a 16-bit address must be shifted left by one to represent the true address. For a 32-bit address the value must be shifted left by two; and for a 64-bit address, the value must be shifted left by three bits.

For a single-bit error, the `SERRADDRx` register logs the error address only if the single-bit error interrupt generation is enabled. Every double-bit error is logged if the ECC controller is enabled.

For true dual-port memory, two sets of recent error address registers are present. Each register shows the address of the error that has occurred on its corresponding memory port.

Related Information

[ECC Structure](#) on page 1088

Refer to the "ECC Structure" section for more information regarding ECC Structure and Hamming Code word lengths.

12.4.5.2. Single-Bit Error Occurrence

The ECC controller has a 32-bit wide counter that increments on every occurrence of a single-bit error.

You can program the ECC controller to trigger an interrupt when the single-bit error counter has reached a specific value, which is configured in the Single-Bit Error Count (`SERRCNTREG`) register. You can reset the counter by clearing the `CNT_RSTA` bit in the ECC Control (`CTRL`) register.

For true dual-port memory, such as SD/MMC, two internal single-bit error counters are present in its ECC controller. Each counter counts the errors on its own memory port. However, both counters refer to the same user-configurable threshold for interrupt generation. In this case, program the counter threshold value in the `SERRCNTREG` register to represent the average number of errors of both memories.

12.4.5.3. Single-Bit Error Look-Up Table

The ECC controller of each memory port has a look-up table (LUT) that logs the memory addresses of all unique single-bit error occurrences. Repeated errors at the same memory address are not stored. The LUT keeps track of single-bit errors, but not double-bit errors.

The most significant bit (MSB) of each entry in the LUT is the valid bit. Whenever a single-bit error occurs and is logged by the LUT, the valid bit is set. The rest of the bits in a single LUT entry contain the memory address of the data error. After the memory address has been read from the LUT, software can clear the entry by writing a 1 to the valid bit in the entry. If all of the LUT entries are occupied and valid bits have not been

cleared, overflow occurs on the next single-bit error. An interrupt can be generated on a LUT overflow. For more information about interrupts, refer to the "ECC Controller Interrupts" section.

The table below lists the LUT depth for every ECC-protected memory in the HPS.

Table 141. LUT Depth for HPS ECC Memories

Peripheral	LUT Depth (entries)
On-chip RAM	16
USB	8
SD/MMC	4 x 2 ⁽²⁵⁾
Ethernet MAC (Rx FIFO)	4
Ethernet MAC (Tx FIFO)	4
DMA	4
NAND (ECC Buffer)	4
NAND (Write FIFO)	4
NAND (Read FIFO)	4
QSPI	4

The LUT entries are located in the ECC controller register map. Software can read the LUT error address and clear the valid bits. For more information, refer to the *ECC Controller Address Map and Register Description* section.

12.4.6. ECC Controller Interrupts

The ECC controller has the ability to generate single- and double-bit error interrupts to the System Manager.

The ECC controller interrupt mechanism involves the System Manager, generic interrupt controller (GIC) and the Arm Cortex-A9 . The following steps outline the interrupt generation process when interrupts have been enabled through the Error Interrupt Enable (ERRINTEN) register.

⁽²⁵⁾ The ECC controller for SD/MMC peripheral has two LUTs, 4-entries deep, because the memory used for the SD/MMC controller is a true dual-port type, where both ports can perform read operations. Reading either of the ports can trigger a single-bit error and so, a LUT is required for each of the ports.

1. The ECC controller generates an interrupt when an error occurs and notifies the System Manager.
2. The System Manager updates its interrupt status register and sends the interrupt to the GIC.
3. The GIC sends the interrupt to the MPU.
4. The MPU services the interrupt and clears the interrupt in the ECC controller.
5. The System Manager clears the interrupt to the GIC and the corresponding interrupt status bit.

12.4.6.1. Single-Bit Error Interrupts

The Single-Bit Error Interrupt Enable (`ERRINTEN`) register must be configured for single-bit error interrupt generation.

For true dual port memory, a separate interrupt is generated for errors on each memory port.

The ECC controller can generate a single-bit error interrupt for:

- All single-bit errors
- LUT overflow
- Single-bit error counter match

The address of the most recent single-bit error is logged in the Single-Bit Error Address (`SERRADDRx`) register.

The interrupt status (`INSTAT`) register indicates if a single-bit error is pending in the ECC controller. All single-bit interrupts are cleared by clearing the single-bit error pending bit of the `INTSTAT` register. The single-bit interrupt generation can be disabled by setting the error interrupt reset bit of the Error Interrupt Reset (`ERRINTENR`) register.

Related Information

[ECC Controller Address Map and Register Descriptions](#) on page 1103

12.4.6.1.1. All Single-Bit Error Interrupt

To generate an interrupt for every single-bit error that occurs, regardless of whether it is with a new or repeated memory address access, you must:

- Clear the `INTMODE` bit in the Interrupt Mode (`INTMODE`) register
- Enable the interrupt by setting the `SERRINTEN` bit of the Error Interrupt Enable (`ERRINTEN`) register

This mode generates the most frequent interrupts and therefore, consumes greater processor cycle resources to service all the interrupts.

Note: Overflow data is not logged in this interrupt configuration.

12.4.6.1.2. LUT Overflow Interrupt

The LUT table can be used to generate two types of interrupts.

On every single-bit error detection and correction, the address of the error is logged in the LUT. Each address logged is unique and is at the data word boundary of its RAM bank. Coherency of the address table is maintained by a valid bit.

An interrupt can be generated for each new LUT entry or only when the LUT overflows. The following table describes the interrupt result based on the `INTMODE` and `INTONOVF` values in the `INTMODE` register. In this table, it is assumed that interrupts have been enabled by setting the `SERRINTEN` bit of the Error Interrupt Enable (`ERRINTEN`) register.

Note: If the `INTMODE` bit is clear, then all errors generate an interrupt and no overflow data is logged. The `INTMODE` bit must be set to 1 for the LUT to log entries.

Table 142. LUT Overflow Interrupt Configuration Options

INTMODE value	INTONOVF value	Result
0	X = Don't care	All errors generate an interrupt. No overflow data is logged.
1	0	An interrupt is generated for each new LUT entry. Overflow detection is disabled. Example: For a four-entry LUT, an interrupt asserts for each unique address entered in the LUT.
1	1	An interrupt is generated only when the LUT overflows. Example: If the LUT depth is four, the occurrence of the fifth unique address causes an interrupt to assert.

12.4.6.1.3. Counter Match Interrupt

The counter match interrupt allows you to set a threshold for the number of single-bit errors captured before an interrupt flag is set.

The `INTONCMP` bit in the `INTMODE` register enables the internal counter to count and compare against the `SERRCNT` value in the Single-Bit Error Count (`SERRCNTREG`) register. The internal counter increments on every single-bit error, regardless of whether it is a new or repeated address. The `INTONCMP` bit has no influence on the `INTMODE` and `INTONOVF` bits of the `INTMODE` register. As long as the internal counter is less than the Single-Bit Error Count (`SERRCNTREG`) register value, no interrupt is generated. When the internal counter is greater than or equal to the `SERRCNTREG` value, a single-bit interrupt request is asserted, the `CMPFLGx` bit is set in the Mode Status (`MODSTAT`) register, and the `SERRPENx` bit is set in the Interrupt Status (`INTSTAT`) register. When the match occurs, additional errors do not increment the counter until the `CMPFLGx` bit is cleared in the `MODSTAT` register.

This resultant match can be handled in three ways:

- Reset the error counter without restarting it. The ECC controller does not count single-bit errors until you restart the counter. Set the CNT_RSTx bit in the CTRL register to 1, which clears the counter. The CMPFLGx bit remains set. The counter does not increment until the CMPFLGx bit is cleared.
- Reset and restart the counter and clear the compare flag. Set CNT_RSTx bit in the CTRL register to 1, which clears the counter. Write a 1 to the CMPFLGx bit, which clears it. The internal counter begins counting from zero.
- Set the count to a higher value and clear the compare flag. Write the SERRCNTREG value to a higher value than the initial compare match value. Write a 1 to the CMPFLGx bit. This clears the CMPFLGx bit, but the internal counter is not reset and the count continues from where it left off until it reaches the new SERRCNTREG value.

If you allow the counter to resume during your interrupt service routine (ISR), it is possible that the error counter could run out again before the ISR exits. If this happens, and you clear the interrupt and exit the ISR, you will never detect the new counter match condition. To avoid this problem, check the CMPFLGx bit in the MODSTAT register prior to exiting the ISR. If CMPFLGx indicates another counter match condition, ensure that you handle it.

To clear the single-bit error interrupt, set the SERRPENx bit in the INTSTAT register.

Related Information

[ECC Controller Address Map and Register Descriptions](#) on page 1103

12.4.6.2. Double-Bit Error Interrupt

All double-bit errors generate interrupts and the error memory address is logged into the recent double-bit error (DERRADDRx) register.

The Interrupt Status (INTSTAT) register indicates if a double-bit error has occurred. The double-bit error interrupt generation cannot be disabled. The interrupt is de-asserted by writing to the double-bit error pending bit of the INTSTAT register.

Related Information

[ECC Controller Address Map and Register Descriptions](#) on page 1103

12.4.6.3. Interrupt Testing

The ECC controller allows you to test the interrupt assertion and de-assertion to check if the interrupt logic is functioning properly. Set the single-or double-bit error test bits in the Interrupt Test (INTTEST) register to assert the corresponding interrupt. To clear the interrupt, set the single- or double-bit error pending bits in the Interrupt Status (INTSTAT) register.

12.4.7. ECC Controller Initialization and Configuration

The steps for initializing and configuring an ECC controller are as follows:

1. Turn off ECC interrupts by setting interrupt masks in the `ecc_intmask_set` register in the System Manager and disabling interrupts in the `ERRINTEN` register of the ECC Controller.
2. Ensure the ECC detection and correction logic is disabled by clearing the `ECC_EN` bit in the `CTRL` register.
3. Enable memory initialization through the ECC controller's memory initialization block by setting the `INITx` bit in the `CTRL` register. If the memory is dual-ported, initialization must be performed on both ports. Refer to the *ECC Structure* section to identify what type of memory you are initializing.
4. When the `INITCOMPLETEx` bit in the `INITSTAT` register is set, configure any single-bit, count, or compare match interrupts that are required. Enable ECC interrupts in the ECC controller and System Manager. Refer to the *ECC Controller Interrupts* section and the System Manager chapter for information on enabling interrupts.
5. (Optional) Test the ECC to see if it is functioning as expected. You can perform tests with or without the ECC controller enabled.

Software can write to the control, data, and address registers provided in the ECC controller and then set the `ENBUSx` bit of the `ECC_startacc` register to initiate memory accesses. Alternatively, software can enable the ECC controller by setting the `ECC_EN` bit in the `CTRL` register and test the memory slave interface. Please refer to the *Memory Testing* section for more information on how to test the ECC controller.

If optional testing is completed, clear the test memory.

After these steps are complete, normal accesses can occur.

When an ECC controller is enabled:

- The ECC controller writes the ECC bits whenever data is written to the RAM.
- Error interrupt requests can be enabled in the Interrupt Mode (`INTMODE`) register.
- Data errors are detected and correction is attempted.

The ECC calculation can only be performed when there is a valid RAM access.

12.4.8. ECC Controller Clocks

The ECC controller for each ECC-protected memory operates at the same clock frequency as its associated RAM port.

The ECC register interface, however, is in the `l4_mp_clk` domain. The clock source names for each ECC controller and its RAM are determined by the specific peripheral.

Table 143. Clock Source for Each ECC Controller and Memory

ECC Memory	Functional Clock
On-chip RAM	l3_main_free_clk
USB	asynchronous l4_mp_clk
SD/MMC	Port A read and write: cclk_in
	Port B read and write: l4_mp_clk
Ethernet MAC (Rx FIFO)	Read: ap_clk
	Write: clk_rx_int
Ethernet MAC (Tx FIFO)	Read: ap_clk
	Write: clk_tx_int
DMA	l4_main_clk
NAND (ECC Buffer)	nand_clk
NAND (Write FIFO)	Write: nand_x_clk
	Read: nand_clk
NAND (Read FIFO)	Read: nand_x_clk
	Write: nand_clk
QSPI	l4_mp_clk

0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

12.5.1.6. ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0814
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1014
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1814

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTS 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

12.5.1.7. ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0818
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1018
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1818

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRI NTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

12.5.1.8. INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C081C
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C101C
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C181C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTON CMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTON OVF 0x0	Reserved							INTMO DE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

12.5.1.9. INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0820
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1020
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1820

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERR A 0x0	Reserved							TSERR A 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

12.5.1.11. MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0828
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1028
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1828

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														CMPFLGA 0x0	

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

12.5.1.12. DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C082C
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C102C
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C182C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				Address 0x0											

DERRADDRA Fields

Bit	Name	Description	Access	Reset
11:0	Address	Recent double-bit error address.	RO	0x0

12.5.1.13. SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0830
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1030
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1830

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				Address 0x0											

SERRADDRA Fields

Bit	Name	Description	Access	Reset
11:0	Address	Recent single-bit error address.	RO	0x0

12.5.1.14. SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C083C
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C103C
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C183C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

12.5.1.32. SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0890
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1090
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1890

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				Address RO 0x0											

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
11:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

12.5.2. emac_tx_ecc Address Map

Module Instance	Base Address	End Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0FFF
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C17FF
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1FFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description

Register	Offset	Width	Access	Reset Value	Description
ECC_RDataecc0bus on page 1177	0x64	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_RDataecc1bus on page 1178	0x68	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc0bus on page 1179	0x6C	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc1bus on page 1180	0x70	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_dbytectrl on page 1181	0x74	32	RW	0x0	Max number of implemented byte enabled is DAT/8
ECC_accctrl on page 1182	0x78	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_startacc on page 1182	0x7C	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_wdctrl on page 1183	0x80	32	RW	0x0	Bits to Enable/Disable Watch Dog Timer
SERRLKUPA0 on page 1184	0x90	32	RW	0x0	Single-bit error address in LOOKUP TABLE for PORTA.
INTSTAT on page 1185	0x	32	RW	0x0	This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this bit is enabled, serr_req signal will be asserted.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

12.5.2.6. ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C14
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1414
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C14

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														SERRINTS 0x0	

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

12.5.2.7. ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C18
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1418
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C18

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														SERRI NTR 0x0	

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

12.5.2.8. INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C1C
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C141C
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C1C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved														INTON CMP 0x0	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTON OVF 0x0	Reserved							INTMO DE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

12.5.2.9. INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C24
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1424
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C24

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERR A 0x0	Reserved						TSERR A 0x0	

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

12.5.2.10. MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C28
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1428
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C28

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

12.5.2.11. DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C2C
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C142C
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C2C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Address 0x0							

DERRADDRA Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent double-bit error address.	RO	0x0

12.5.2.12. SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C30
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1430
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C30

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Address 0x0							

SERRADDRA Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent single-bit error address.	RO	0x0

12.5.2.13. SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C3C
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C143C
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C3C

Offset: 0x3C

Access: RW

Bit Fields

VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Address RO 0x0							

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
9:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

12.5.2.32. INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C32
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1432
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C32

Offset: 0x32

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

12.5.3.7. ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2018

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRI NTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

12.5.3.8. INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C201C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTON CMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTON OVF 0x0	Reserved							INTMO DE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

12.5.3.9. INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2020

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRP ENA 0x0	Reserved							SERRP ENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

12.5.3.10. INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2024

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERR A 0x0	Reserved						TSERR A 0x0	

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

12.5.3.11. MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2028

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

12.5.3.12. DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C202C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							Address 0x0								

DERRADDRA Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent double-bit error address.	RO	0x0

12.5.3.13. SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2030

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Address 0x0							

SERRADDRA Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent single-bit error address.	RO	0x0

12.5.3.14. SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C203C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

12.5.3.15. ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2040

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								ECC_AddrBUS 0x0							

ECC_Addrbus Fields

Bit	Name	Description	Access	Reset
9:0	ECC_AddrBUS	Address will be driven to RAM to either read or write the data. Address will be latched by the RAM when the Enbus is asserted.	RW	0x0

12.5.3.16. ECC_RData0bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2044

Offset: 0x44

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

5:0	ECC_WDataecc4BUS	Eccdata from the register will be written to the RAM.	WO	0x0

12.5.3.28. ECC_dbytectl

ECC Data Byte Control. The maximum number of implemented byte enables equals the data width of the RAM divided by 8.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2074

Offset: 0x74

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															DBEN 0x0

ECC_dbytectl Fields

Bit	Name	Description	Access	Reset
0	DBEN	Byte or word enable for access.	RW	0x0

12.5.3.29. ECC_accctrl

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2078

Offset: 0x78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							RDWR 0x0	Reserved					ECCOV R 0x0	DATAO VR 0x0	

ECC_acctrl Fields

Bit	Name	Description	Access	Reset
8	RDWR	Control for read/write.	RW	0x0
1	ECCOVR	ECC Data Override.	RW	0x0
0	DATAOVR	RAM Data Override. Override the ECC_dataBUS register with RAM data in read mode set by ECC_RW. 1'b0: Data override disabled. 1'b1: Data override enabled.	RW	0x0

12.5.3.30. ECC_startacc

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C207C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															ENBUS A 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0

12.5.3.31. ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2080

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_ RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

12.5.3.32. SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2090

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address RO 0x0									

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
9:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

12.5.4. nandr_ecc Address Map

Module Instance	Base Address	End Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C27FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 1222	0x0	32	RO	0x0

12.5.4.2. IP_REV_ID

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2400

Offset: 0x0

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SIREV RO 0x0															

IP_REV_ID Fields

Bit	Name	Description	Access	Reset
15:0	SIREV	IP Rev # These bits indicate the silicon revision number.	RO	0x0

12.5.4.3. CTRL

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2408

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INITA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CNT_R STA 0x0	Reserved							ECC_E N 0x0

CTRL Fields

Bit	Name	Description	Access	Reset
16	INITA	Enable for the hardware memory initialization PORTA.	RW	0x0
8	CNT_RSTA	Enable to reset internal single-bit error counter A value to zero	RW	0x0
0	ECC_EN	Enable for the ECC detection and correction logic.	RW	0x0

12.5.4.4. INITSTAT

This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C240C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															INITC OMPLE TEA 0x0

INITSTAT Fields

Bit	Name	Description	Access	Reset
0	INITCOMPLETEA	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0

12.5.4.5. ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2410

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRI NTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

12.5.4.6. ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2414

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRI NTR 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

12.5.4.7. ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2418

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRI NTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

12.5.4.8. INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C241C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTON CMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTON OVF 0x0	Reserved							INTMO DE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

12.5.4.9. INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2420

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRP ENA 0x0	Reserved						SERRP ENA 0x0	

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

12.5.4.10. INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2424

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERR A 0x0	Reserved							TSERR A 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

12.5.4.11. MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2428

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														CMPFL GA 0x0	

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

12.5.4.12. DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C242C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											Address 0x0				

DERRADDRA Fields

Bit	Name	Description	Access	Reset
4:0	Address	Recent double-bit error address.	RO	0x0

12.5.4.13. SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2430

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											Address 0x0				

SERRADDRA Fields

Bit	Name	Description	Access	Reset
4:0	Address	Recent single-bit error address.	RO	0x0

12.5.4.14. SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C243C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

12.5.4.15. ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2440

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											ECC_AddrBUS 0x0				

ECC_Addrbus Fields

Bit	Name	Description	Access	Reset
4:0	ECC_AddrBUS	Address will be driven to RAM to either read or write the data. Address will be latched by the RAM when the Enbus is asserted.	RW	0x0

12.5.4.16. ECC_RData0bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2444

Offset: 0x44

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_RDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC_RDataBUS 0x0															

ECC_RData0bus Fields

Bit	Name	Description	Access	Reset
31:0	ECC_RDataBUS	ECC_RDataBUS[31:0].	RO	0x0

12.5.4.17. ECC_RData1bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2448

Offset: 0x48

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_RDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC_RDataBUS 0x0															

ECC_RData1bus Fields

Bit	Name	Description	Access	Reset
31:0	ECC_RDataBUS	ECC_RDataBUS[63:32].	RO	0x0

12.5.4.18. ECC_RData2bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C244C

Offset: 0x4C

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_RDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC_RDataBUS 0x0

6:0	ECC_WDataecc4BUS	Eccdata from the register will be written to the RAM.	WO	0x0

12.5.4.28. ECC_dbytectl

ECC Data Byte Control. The maximum number of implemented byte enables equals the data width of the RAM divided by 8.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2474

Offset: 0x74

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															DBEN 0x0

ECC_dbytectl Fields

Bit	Name	Description	Access	Reset
0	DBEN	Byte or word enable for access.	RW	0x0

12.5.4.29. ECC_accctrl

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2478

Offset: 0x78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							RDWR 0x0	Reserved					ECCOV R 0x0	DATAO VR 0x0	

ECC_acctrl Fields

Bit	Name	Description	Access	Reset
8	RDWR	Control for read/write.	RW	0x0
1	ECCOVR	ECC Data Override.	RW	0x0
0	DATAOVR	RAM Data Override. Override the ECC_dataBUS register with RAM data in read mode set by ECC_RW. 1'b0: Data override disabled. 1'b1: Data override enabled.	RW	0x0

12.5.4.30. ECC_startacc

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C247C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															ENBUS A 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0

12.5.4.31. ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2480

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_ RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

12.5.4.32. SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2490

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											Address RO 0x0				

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
4:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

12.5.5. nandw_ecc Address Map

Module Instance	Base Address	End Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2BFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 1250	0x0	32	RO	0x0	
CTRL on page 1250	0x8	32	RW	0x0	ECC Control Register
INITSTAT on page 1251	0xC	32	RW	0x0	This bit is used to set the initialize the memory and ecc to a known value
ERRINTEN on page 1252	0x10	32	RW	0x0	Error Interrupt enable
ERRINTENS on page 1252	0x14	32	RW	0x0	Error Interrupt set
ERRINTENR on page 1253	0x18	32	RW	0x0	Error Interrupt reset.
INTMODE on page 1254	0x1C	32	RW	0x0	Reads reflect SERRINTEN.
INTSTAT on page 1255	0x20	32	RW	0x0	This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this bit is enabled, serr_req signal will be asserted.
INTTEST on page 1255	0x24	32	RW	0x0	This bits is used to test interrupt from ECC RAM to GIC
MODSTAT on page 1256	0x28	32	RW	0x0	Counter feature status flag
DERRADDRA on page 1257	0x2C	32	RO	0x0	This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.
SERRADDRA on page 1257	0x30	32	RO	0x0	This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.
SERRCNTREG on page 1258	0x3C	32	RW	0x0	Maximum counter value for single-bit error interrupt
ECC_Addrbus on page 1258	0x40	32	RW	0x0	MSB bit of address is determined by ADR.
continued...

12.5.5.2. IP_REV_ID

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2800

Offset: 0x0

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SIREV RO 0x0															

IP_REV_ID Fields

Bit	Name	Description	Access	Reset
15:0	SIREV	IP Rev # These bits indicate the silicon revision number.	RO	0x0

12.5.5.3. CTRL

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2808

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INITA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CNT_R STA 0x0	Reserved							ECC_E N 0x0

CTRL Fields

Bit	Name	Description	Access	Reset
16	INITA	Enable for the hardware memory initialization PORTA.	RW	0x0
8	CNT_RSTA	Enable to reset internal single-bit error counter A value to zero	RW	0x0
0	ECC_EN	Enable for the ECC detection and correction logic.	RW	0x0

12.5.5.4. INITSTAT

This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C280C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															INITC OMPLE TEA 0x0

INITSTAT Fields

Bit	Name	Description	Access	Reset
0	INITCOMPLETEA	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0

12.5.5.5. ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2810

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														SERRI NTEN	0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

12.5.5.6. ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2814

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRI NTR 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

12.5.5.7. ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2818

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRI NTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

12.5.5.8. INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C281C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTON CMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTON OVF 0x0	Reserved							INTMO DE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

12.5.5.9. INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2820

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRP ENA 0x0	Reserved							SERRP ENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

12.5.5.10. INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2824

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERR A 0x0	Reserved							TSERR A 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

12.5.5.11. MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2828

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														CMPFL GA 0x0	

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

12.5.5.12. DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C282C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									Address 0x0						

DERRADDRA Fields

Bit	Name	Description	Access	Reset
6:0	Address	Recent double-bit error address.	RO	0x0

12.5.5.13. SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2830

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									Address 0x0						

SERRADDRA Fields

Bit	Name	Description	Access	Reset
6:0	Address	Recent single-bit error address.	RO	0x0

12.5.5.14. SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C283C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

12.5.5.15. ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2840

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									ECC_AddrBUS 0x0						

ECC_Addrbus Fields

Bit	Name	Description	Access	Reset
6:0	ECC_AddrBUS	Address will be driven to RAM to either read or write the data. Address will be latched by the RAM when the Enbus is asserted.	RW	0x0

12.5.5.16. ECC_RData0bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2844

Offset: 0x44

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_RDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC_RDataBUS 0x0															

ECC_RData0bus Fields

Bit	Name	Description	Access	Reset
31:0	ECC_RDataBUS	ECC_RDataBUS[31:0].	RO	0x0

12.5.5.17. ECC_RData1bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2848

Offset: 0x48

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_RDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC_RDataBUS 0x0															

ECC_RData1bus Fields

Bit	Name	Description	Access	Reset
31:0	ECC_RDataBUS	ECC_RDataBUS[63:32].	RO	0x0

12.5.5.18. ECC_RData2bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C284C

Offset: 0x4C

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_RDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC_RDataBUS 0x0															

ECC_RData2bus Fields

Bit	Name	Description	Access	Reset
31:0	ECC_RDataBUS	ECC_RDataBUS[95:64].	RO	0x0

12.5.5.19. ECC_RData3bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2850

Offset: 0x50

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_RDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC_RDataBUS 0x0															

ECC_RData3bus Fields

Bit	Name	Description	Access	Reset
31:0	ECC_RDataBUS	ECC_RDataBUS[127-96].	RO	0x0

12.5.5.20. ECC_WData0bus

Data from the register will be written to the RAM.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2854

Offset: 0x54

Access: WO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_WDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC_WDataBUS 0x0															

ECC_WData0bus Fields

Bit	Name	Description	Access	Reset
31:0	ECC_WDataBUS	ECC_WDataBUS[31:0].	WO	0x0

12.5.5.21. ECC_WData1bus

Data from the register will be written to the RAM.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2858

Offset: 0x58

Access: WO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

6:0	ECC_WDataecc4BUS	Eccdata from the register will be written to the RAM.	WO	0x0

12.5.5.28. ECC_dbytectl

ECC Data Byte Control. The maximum number of implemented byte enables equals the data width of the RAM divided by 8.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2874

Offset: 0x74

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															DBEN 0x0

ECC_dbytectl Fields

Bit	Name	Description	Access	Reset
0	DBEN	Byte or word enable for access.	RW	0x0

12.5.5.29. ECC_accctrl

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2878

Offset: 0x78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							RDWR 0x0	Reserved					ECCOV R 0x0	DATAO VR 0x0	

ECC_acctrl Fields

Bit	Name	Description	Access	Reset
8	RDWR	Control for read/write.	RW	0x0
1	ECCOVR	ECC Data Override.	RW	0x0
0	DATAOVR	RAM Data Override. Override the ECC_dataBUS register with RAM data in read mode set by ECC_RW. 1'b0: Data override disabled. 1'b1: Data override enabled.	RW	0x0

12.5.5.30. ECC_startacc

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C287C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															ENBUS A 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0

12.5.5.31. ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2880

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_ RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

12.5.5.32. SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2890

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									Address RO 0x0						

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
6:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

12.5.6. sdmmc_ecc Address Map

Module Instance	Base Address	End Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2FFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 1278	0x0	32	RO	0x0	
CTRL on page 1279	0x8	32	RW	0x0	ECC Control Register
INITSTAT on page 1280	0xC	32	RW	0x0	This bit is used to set the initialize the memory and ecc to a known value
ERRINTEN on page 1281	0x10	32	RW	0x0	Error Interrupt enable
ERRINTENS on page 1281	0x14	32	RW	0x0	Error Interrupt set
ERRINTENR on page 1282	0x18	32	RW	0x0	Error Interrupt reset.
INTMODE on page 1283	0x1C	32	RW	0x0	Reads reflect SERRINTEN.
INTSTAT on page 1283	0x20	32	RW	0x0	This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this bit is enabled, serr_req signal will be asserted.
INTTEST on page 1284	0x24	32	RW	0x0	This bits is used to test interrupt from ECC RAM to GIC
MODSTAT on page 1285	0x28	32	RW	0x0	Counter feature status flag
DERRADDRA on page 1286	0x2C	32	RO	0x0	This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.
SERRADDRA on page 1286	0x30	32	RO	0x0	This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.
DERRADDRB on page 1287	0x34	32	RO	0x0	This register shows the address of PORTB current double-bit error. RAM size will determine the maximum number of address bits.
SERRADDRB on page 1288	0x38	32	RO	0x0	This register shows the address of PORTB current single-bit error. RAM size will determine the maximum number of address bits.
continued...					

Register	Offset	Width	Access	Reset Value	Description
SERRCNTREG on page 1288	0x3C	32	RW	0x0	Maximum counter value for single-bit error interrupt
ECC_Addrbus on page 1289	0x40	32	RW	0x0	MSB bit of address is determined by ADR.
ECC_RData0bus on page 1290	0x44	32	RO	0x0	Data will be read to this register field.
ECC_RData1bus on page 1290	0x48	32	RO	0x0	Data will be read to this register field.
ECC_RData2bus on page 1291	0x4C	32	RO	0x0	Data will be read to this register field.
ECC_RData3bus on page 1291	0x50	32	RO	0x0	Data will be read to this register field.
ECC_WData0bus on page 1292	0x54	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData1bus on page 1292	0x58	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData2bus on page 1293	0x5C	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData3bus on page 1293	0x60	32	WO	0x0	Data from the register will be written to the RAM.
ECC_RDataecc0bus on page 1294	0x64	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_RDataecc1bus on page 1295	0x68	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc0bus on page 1296	0x6C	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
continued...					

Register	Offset	Width	Access	Reset Value	Description
ECC_WDataeccibus on page 1297	0x70	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_dbytectrl on page 1298	0x74	32	RW	0x0	Max number of implemented byte enabled is DAT/8
ECC_accctrl on page 1298	0x78	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_startacc on page 1299	0x7C	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.

12.5.6.2. IP_REV_ID

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C00

Offset: 0x0

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SIREV RO 0x0															

IP_REV_ID Fields

Bit	Name	Description	Access	Reset
15:0	SIREV	IP Rev # These bits indicate the silicon revision number.	RO	0x0

12.5.6.3. CTRL

ECC Control Register

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C08

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							INITB 0x0	Reserved							INITA 0x0

Reserved						CNT_R STB 0x0	CNT_R STA 0x0	Reserved							ECC_E N 0x0

CTRL Fields

Bit	Name	Description	Access	Reset
24	INITB	Enable for the hardware memory initialization PORTB.	RW	0x0
16	INITA	Enable for the hardware memory initialization PORTA.	RW	0x0

continued...

Bit	Name	Description	Access	Reset
9	CNT_RSTB	Enable to reset internal single-bit error counter B value to zero	RW	0x0
8	CNT_RSTA	Enable to reset internal single-bit error counter A value to zero	RW	0x0
0	ECC_EN	Enable for the ECC detection and correction logic.	RW	0x0

12.5.6.4. INITSTAT

This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C0C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INITC OMPLE TEB 0x0	Reserved							INITC OMPLE TEA 0x0

INITSTAT Fields

Bit	Name	Description	Access	Reset
8	INITCOMPLETEB	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0
0	INITCOMPLETEA	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0

12.5.6.5. ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C10

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRI NTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

12.5.6.6. ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C14

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														SERRINTS 0x0	

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

12.5.6.7. ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C18

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														SERRINTR 0x0	

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTENR. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTENR bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

12.5.6.8. INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C1C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTON CMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTON OVF 0x0	Reserved							INTMO DE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

12.5.6.9. INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C20

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							DERRP ENB 0x0	Reserved							SERRP ENB 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRP ENA 0x0	Reserved							SERRP ENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
24	DERRPENB	Double-bit error pending PORTB.	RW	0x0
16	SERRPENB	Single-bit error pending for PORTB.	RW	0x0
8	DERRPENB	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENB	Single-bit error pending for PORTA.	RW	0x0

12.5.6.10. INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C24

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							TDERR B 0x0	Reserved							TSERR B 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERR A 0x0	Reserved							TSERR A 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
24	TDERRB	Test PORTB Double-bit error.	RW	0x0
16	TSERRB	Test PORTB Single-bit error.	RW	0x0
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

12.5.6.11. MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C28

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													CMPFL GB 0x0	CMPFL GA 0x0	

**MODSTAT Fields**

Bit	Name	Description	Access	Reset
1	CMPFLGB	Port B compare status flag	RW	0x0
0	CMPFLGA	Port A compare status flag	RW	0x0

12.5.6.12. DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C2C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							Address 0x0								

DERRADDRA Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent double-bit error address.	RO	0x0

12.5.6.13. SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C30

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Address 0x0							

SERRADDRA Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent single-bit error address.	RO	0x0

12.5.6.14. DERRADDRB

This register shows the address of PORTB current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C34

Offset: 0x34

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Address 0x0							

DERRADDRB Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent double-bit error address.	RO	0x0

12.5.6.15. SERRADDRB

This register shows the address of PORTB current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C38

Offset: 0x38

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							Address 0x0								

SERRADDRB Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent single-bit error address.	RO	0x0

12.5.6.16. SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C3C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

12.5.6.17. ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C40

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						ECC_AddrBUS 0x0									

ECC_Addrbus Fields

Bit	Name	Description	Access	Reset
9:0	ECC_AddrBUS	Address will be driven to RAM to either read or write the data. Address will be latched by the RAM when the Enbus is asserted.	RW	0x0

12.5.6.18. ECC_RData0bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C44

Offset: 0x44

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_RDataBUS 0x0

6:0	ECC_WDataecc4BUS	Eccdata from the register will be written to the RAM.	WO	0x0

12.5.6.30. ECC_dbyectl

ECC Data Byte Control. The maximum number of implemented byte enables equals the data width of the RAM divided by 8.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C74

Offset: 0x74

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														DBEN	0x0

ECC_dbyectl Fields

Bit	Name	Description	Access	Reset
0	DBEN	Byte or word enable for access.	RW	0x0

12.5.6.31. ECC_acctrl

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C78

Offset: 0x78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							RDWR 0x0	Reserved					ECCOV R 0x0	DATAO VR 0x0	

ECC_acctrl Fields

Bit	Name	Description	Access	Reset
8	RDWR	Control for read/write.	RW	0x0
1	ECCOVR	ECC Data Override.	RW	0x0
0	DATAOVR	RAM Data Override. Override the ECC_dataBUS register with RAM data in read mode set by ECC_RW. 1'b0: Data override disabled. 1'b1: Data override enabled.	RW	0x0

12.5.6.32. ECC_startacc

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C7C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															ENBUS A 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															ENBUS B 0x0

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0
0	ENBUSB	Start RAM access for PORTB.	RW	0x0

12.5.6.33. ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C80

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_ RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

12.5.6.34. SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C90

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address RO 0x0									

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
9:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

12.5.6.35. SERRLKUPB0

Single-bit error address in LOOKUP TABLE for PORTB.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2CD0

Offset: 0xD0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Address RO 0x0							

SERRLKUPB0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
9:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

12.5.7. onchip_ram_ecc Address Map

Module Instance	Base Address	End Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C7FFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 1309	0x0	32	RO	0x0	
CTRL on page 1310	0x8	32	RW	0x2	ECC Control Register
INITSTAT on page 1311	0xC	32	RW	0x0	This bit is used to set the initialize the memory and ecc to a known value
ERRINTEN on page 1312	0x10	32	RW	0x0	Error Interrupt enable
continued...					

Register	Offset	Width	Access	Reset Value	Description
ERRINTENS on page 1312	0x14	32	RW	0x0	Error Interrupt set
ERRINTENR on page 1313	0x18	32	RW	0x0	Error Interrupt reset.
INTMODE on page 1314	0x1C	32	RW	0x0	Reads reflect SERRINTEN.
INTSTAT on page 1314	0x20	32	RW	0x0	This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this bit is enabled, serr_req signal will be asserted.
INTTEST on page 1315	0x24	32	RW	0x0	This bits is used to test interrupt from ECC RAM to GIC
MODSTAT on page 1316	0x28	32	RW	0x0	Counter feature status flag
DERRADDR on page 1316	0x2C	32	RO	0x0	This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.
SERRADDR on page 1317	0x30	32	RO	0x0	This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.
SERRCNTREG on page 1318	0x3C	32	RW	0x0	Maximum counter value for single-bit error interrupt
ECC_Addrbus on page 1318	0x40	32	RW	0x0	MSB bit of address is determined by ADR.
ECC_RData0bus on page 1319	0x44	32	RO	0x0	Data will be read to this register field.
ECC_RData1bus on page 1319	0x48	32	RO	0x0	Data will be read to this register field.
ECC_RData2bus on page 1320	0x4C	32	RO	0x0	Data will be read to this register field.
ECC_RData3bus on page 1321	0x50	32	RO	0x0	Data will be read to this register field.
continued...					

Register	Offset	Width	Accesses	Reset Value	Description
ECC_WData0bus on page 1321	0x54	32	WO	0x0	Data from the register will be written to the RAM.

12.5.7.2. IP_REV_ID

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3000

Offset: 0x0

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SIREV RO 0x0															

IP_REV_ID Fields

Bit	Name	Description	Access	Reset
15:0	SIREV	IP Rev # These bits indicate the silicon revision number.	RO	0x0

12.5.7.3. CTRL

ECC Control Register

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INITA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CNT_R STA 0x0	Reserved					ECC_S LVERR _DIS 0x1	ECC_E N 0x0	

CTRL Fields

Bit	Name	Description	Access	Reset
16	INITA	Enable for the hardware memory initialization PORTA.	RW	0x0
8	CNT_RSTA	Enable to reset internal single-bit error counter A value to zero	RW	0x0
1	ECC_SLVERR_DIS	Enable to prevent double-bit ECC error from triggering SLVERR at ONCHIP_RAM AXI Interface RRESP output. Enable = 1'b1 Disable = 1'b0	RW	0x1
0	ECC_EN	Enable for the ECC detection and correction logic.	RW	0x0

12.5.7.4. INITSTAT

This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C300C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															INITCOMPLETEA 0x0

INITSTAT Fields

Bit	Name	Description	Access	Reset
0	INITCOMPLETEA	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0

12.5.7.5. ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3010

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

12.5.7.6. ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3014

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTS 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

12.5.7.7. ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3018

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

12.5.7.8. INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C301C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTON CMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTON OVF 0x0	Reserved							INTMO DE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

12.5.7.9. INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3020

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRP ENA 0x0	Reserved							SERRP ENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

12.5.7.10. INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3024

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERR A 0x0	Reserved							TSERR A 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

12.5.7.11. MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3028

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

12.5.7.12. DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C302C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	Address 0x0														

DERRADDRA Fields

Bit	Name	Description	Access	Reset
14:0	Address	Recent double-bit error address.	RO	0x0

12.5.7.13. SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3030

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	Address 0x0														

SERRADDRA Fields

Bit	Name	Description	Access	Reset
14:0	Address	Recent single-bit error address.	RO	0x0

12.5.7.14. SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C303C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

12.5.7.15. ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3040

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	ECC_AddrBUS 0x0														

ECC_Addrbus Fields

Bit	Name	Description	Access	Reset
14:0	ECC_AddrBUS	Address will be driven to RAM to either read or write the data. Address will be latched by the RAM when the Enbus is asserted.	RW	0x0

12.5.7.16. ECC_RData0bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3044

Offset: 0x44

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_RDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC_RDataBUS 0x0															

ECC_RData0bus Fields

Bit	Name	Description	Access	Reset
31:0	ECC_RDataBUS	ECC_RDataBUS[31:0].	RO	0x0

12.5.7.17. ECC_RData1bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3048

Offset: 0x48

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_RDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC_RDataBUS 0x0															

ECC_RData1bus Fields

Bit	Name	Description	Access	Reset
31:0	ECC_RDataBUS	ECC_RDataBUS[63:32].	RO	0x0

12.5.7.18. ECC_RData2bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C304C

Offset: 0x4C

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_RDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC_RDataBUS 0x0															

ECC_RData2bus Fields

Bit	Name	Description	Access	Reset
31:0	ECC_RDataBUS	ECC_RDataBUS[95:64].	RO	0x0

12.5.7.19. ECC_RData3bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3050

Offset: 0x50

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_RDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC_RDataBUS 0x0															

ECC_RData3bus Fields

Bit	Name	Description	Access	Reset
31:0	ECC_RDataBUS	ECC_RDataBUS[127-96].	RO	0x0

12.5.7.20. ECC_WData0bus

Data from the register will be written to the RAM.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3054

Offset: 0x54

Access: WO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_WDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC_WDataBUS 0x0															

**ECC_WData0bus Fields**

Bit	Name	Description	Access	Reset
31:0	ECC_WDataBUS	ECC_WDataBUS[31:0].	WO	0x0

12.5.7.21. ECC_WData1bus

Data from the register will be written to the RAM.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3058

Offset: 0x58

Access: WO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_WDataBUS 0x0

ECC_WDataecc1bus Fields

Bit	Name	Description	Access	Reset
28:2 4	ECC_WDataecc7BUS	Eccdata from the register will be written to the RAM.	WO	0x0
20:1 6	ECC_WDataecc6BUS	Eccdata from the register will be written to the RAM.	WO	0x0
12:8	ECC_WDataecc5BUS	Eccdata from the register will be written to the RAM.	WO	0x0
4:0	ECC_WDataecc4BUS	Eccdata from the register will be written to the RAM.	WO	0x0

12.5.7.28. ECC_dbytectl

ECC Data Byte Control. The maximum number of implemented byte enables equals the data width of the RAM divided by 8.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3074

Offset: 0x74

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								DBEN 0x0							

ECC_dbytectl Fields

Bit	Name	Description	Access	Reset
7:0	DBEN	Byte or word enable for access.	RW	0x0

12.5.7.29. ECC_acctrl

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3078

Offset: 0x78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							RDWR 0x0	Reserved					ECCOVR R 0x0	DATAOVR VR 0x0	

ECC_acctrl Fields

Bit	Name	Description	Access	Reset
8	RDWR	Control for read/write.	RW	0x0
1	ECCOVR	ECC Data Override.	RW	0x0
0	DATAOVR	RAM Data Override. Override the ECC_dataBUS register with RAM data in read mode set by ECC_RW. 1'b0: Data override disabled. 1'b1: Data override enabled.	RW	0x0

12.5.7.30. ECC_startacc

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C307C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															ENBUS_A 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUS_A	Start RAM access for PORTA.	RW	0x0

12.5.7.31. ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3080

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

12.5.7.32. SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3090

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	Address RO 0x0														

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
14:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

12.5.8. dmac_ecc Address Map

Module Instance	Base Address	End Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C83FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 1338	0x0	32	RO	0x0	
CTRL on page 1338	0x8	32	RW	0x0	ECC Control Register
INITSTAT on page 1339	0xC	32	RW	0x0	This bit is used to set the initialize the memory and ecc to a known value
ERRINTEN on page 1340	0x10	32	RW	0x0	Error Interrupt enable
ERRINTENS on page 1340	0x14	32	RW	0x0	Error Interrupt set
ERRINTENR on page 1341	0x18	32	RW	0x0	Error Interrupt reset.
INTMODE on page 1342	0x1C	32	RW	0x0	Reads reflect SERRINTEN.
INTSTAT on page 1343	0x20	32	RW	0x0	This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.
INTTEST on page 1343	0x24	32	RW	0x0	This bits is used to test interrupt from ECC RAM to GIC
MODSTAT on page 1344	0x28	32	RW	0x0	Counter feature status flag
DERRADDRA on page 1345	0x2C	32	RO	0x0	This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.
SERRADDRA on page 1345	0x30	32	RO	0x0	This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.
SERRCNTREG on page 1346	0x3C	32	RW	0x0	Maximum counter value for single-bit error interrupt

SIREV RO 0x0															

IP_REV_ID Fields

Bit	Name	Description	Access	Reset
15:0	SIREV	IP Rev # These bits indicate the silicon revision number.	RO	0x0

12.5.8.3. CTRL

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INITA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CNT_R STA 0x0	Reserved							ECC_E N 0x0

CTRL Fields

Bit	Name	Description	Access	Reset
16	INITA	Enable for the hardware memory initialization PORTA.	RW	0x0
8	CNT_RSTA	Enable to reset internal single-bit error counter A value to zero	RW	0x0
0	ECC_EN	Enable for the ECC detection and correction logic.	RW	0x0

12.5.8.4. INITSTAT

This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C800C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															INITC OMPLE TEA 0x0

INITSTAT Fields

Bit	Name	Description	Access	Reset
0	INITCOMPLETEA	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0

12.5.8.5. ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8010

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														SERRI NTEN 0x0	

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

12.5.8.6. ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8014

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRI NTS 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

12.5.8.7. ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8018

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRI NTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

12.5.8.8. INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C801C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTON CMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTON OVF 0x0	Reserved							INTMO DE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

12.5.8.9. INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8020

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRP ENA 0x0	Reserved						SERRP ENA 0x0	

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

12.5.8.10. INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8024

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERR A 0x0	Reserved							TSERR A 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

12.5.8.11. MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8028

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														CMPFL GA 0x0	

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

12.5.8.12. DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C802C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Address 0x0							

DERRADDRA Fields

Bit	Name	Description	Access	Reset
8:0	Address	Recent double-bit error address.	RO	0x0

12.5.8.13. SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8030

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Address 0x0							

SERRADDRA Fields

Bit	Name	Description	Access	Reset
8:0	Address	Recent single-bit error address.	RO	0x0

12.5.8.14. SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C803C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

12.5.8.15. ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8040

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								ECC_AddrBUS 0x0							

ECC_Addrbus Fields

Bit	Name	Description	Access	Reset
8:0	ECC_AddrBUS	Address will be driven to RAM to either read or write the data. Address will be latched by the RAM when the Enbus is asserted.	RW	0x0

12.5.8.16. ECC_RData0bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8044

Offset: 0x44

Access: RO

Bit Fields

Bit	Name	Description	Access	Reset
31:0	ECC_WDataBUS	ECC_WDataBUS[127-96].	WO	0x0

12.5.8.24. ECC_RDataecc0bus

The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8064

Offset: 0x64

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

4:0	ECC_WDataecc4BUS	Eccdata from the register will be written to the RAM.	WO	0x0

12.5.8.28. ECC_dbytectl

ECC Data Byte Control. The maximum number of implemented byte enables equals the data width of the RAM divided by 8.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8074

Offset: 0x74

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								DBEN 0x0							

ECC_dbytectl Fields

Bit	Name	Description	Access	Reset
7:0	DBEN	Byte or word enable for access.	RW	0x0

12.5.8.29. ECC_accctrl

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8078

Offset: 0x78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							RDWR 0x0	Reserved					ECCOV R 0x0	DATAO VR 0x0	

ECC_acctrl Fields

Bit	Name	Description	Access	Reset
8	RDWR	Control for read/write.	RW	0x0
1	ECCOVR	ECC Data Override.	RW	0x0
0	DATAOVR	RAM Data Override. Override the ECC_dataBUS register with RAM data in read mode set by ECC_RW. 1'b0: Data override disabled. 1'b1: Data override enabled.	RW	0x0

12.5.8.30. ECC_startacc

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C807C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															ENBUS A 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0

12.5.8.31. ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8080

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_ RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

12.5.8.32. SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8090

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Address RO 0x0							

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
8:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

12.5.9. qspi_ecc Address Map

Module Instance	Base Address	End Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C87FF
