continued...

Bit	Name	Description	Access	Reset						
		Set by the DWC_otg core, this bit indicates that this buffer holds 8 bytes of setup data. There is only one Setup packet per buffer. On receiving a Setup packet, the DWC_otg core closes the buffer and disables the corresponding endpoint. The application has to re-enable the endpoint to receive any OUT data for the Control Transfer and reprogram the buffer start address. Note: Because of the above behavior, the DWC_otg core can receive any number of back to back setup packets and one buffer for every setup packet is used. 1'b0: No Setup packet received 1'b1: Setup packet received Reset: 1'b0

doepdma14 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma14	Holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as	RW	0x0

Bit	Name	Description	Access	Reset
		SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.

20. SPI Controller

The hard processor system (HPS) provides two serial peripheral interface (SPI) masters and two SPI slaves. The SPI masters and slaves are instances of the Synopsys DesignWare Synchronous Serial Interface (SSI) controller (DW_apb_ssi). †

20.1. Features of the SPI Controller

The SPI controller has the following features: †

- Serial master and serial slave controllers – Enable serial communication with serial-master or serial-slave peripheral devices. †
- Each SPI master has a maximum bit rate of 60Mbps
- Each SPI slave has a maximum bit rate of 50Mbps
- Serial interface operation – Programmable choice of the following protocols:
 - Motorola SPI protocol
 - Texas Instruments Synchronous Serial Protocol
 - National Semiconductor Microwire
- DMA controller interface integrated with HPS DMA controller
- SPI master supports received serial data bit (RXD) sample delay
- Transmit and receive FIFO buffers are 256 words deep
- SPI master supports up to four slave selects
- Programmable master serial bit rate
- Programmable data item size of 4 to 16 bits
- Support for Multi-master mode

20.2. SPI Block Diagram and System Integration

The SPI supports data bus widths of 32 bits. †

20.2.1. SPI Block Diagram

Figure 139. SPI Block Diagram

The functional groupings of the main interfaces to the SPI block are as follows: †

- System bus interface
- DMA peripheral request interface
- Interrupt interface
- SPI interface

20.3. SPI Controller Signal Description

Signals from the two SPI masters and two SPI slaves can be routed to the FPGA or the HPS I/O pins. The following sections describe the signals available.

20.3.1. Interface to HPS I/O

Two sets of SPI Master and two sets of SPI Slave Pins are available to the HPS I/O. The pin names are shown below. For more information on routing SPI signals to HPS I/O, refer to the *HPS Component Interfaces* chapter.

Table 239. SPI Master Interface Pins

Signal Name	Signal Width	Direction	Description
CLK	1	Out	Serial clock output from the SPI master
MOSI	1	Out	Transmit data line for the SPI master
MISO	1	In	Receive data line for the SPI master
SS0_N	1	Out	Slave Select 0: Slave select signal from SPI master
SS1_N	1	Out	Slave Select 1: Slave select signal from SPI master

Table 240. SPI Slave Interface Pins

Signal Name	Signal Width	Direction	Description
CLK	1	In	Serial clock input to the SPI slave
MOSI	1	In	Receive data line for the SPI slave
MISO	1	Out	Transmit data line for the SPI slave
SS0_N	1	In	Slave select input to the SPI slave

20.4. Functional Description of the SPI Controller

20.4.1. Protocol Details and Standards Compliance

This section describes the functional operation of the SPI controller.

The host processor accesses data, control, and status information about the SPI controller through the system bus interface. The SPI also interfaces with the DMA Controller. †

The HPS includes two general-purpose SPI master controllers and two general-purpose SPI slave controllers.

The SPI controller can connect to any other SPI device using any of the following protocols:

- Motorola SPI Protocol †
- Texas Instruments Serial Protocol (SSP) †
- National Semiconductor Microwire Protocol †

20.4.2. SPI Controller Overview

In order for the SPI controller to connect to a serial-master or serial-slave peripheral device, the peripheral must have a least one of the following interfaces: †

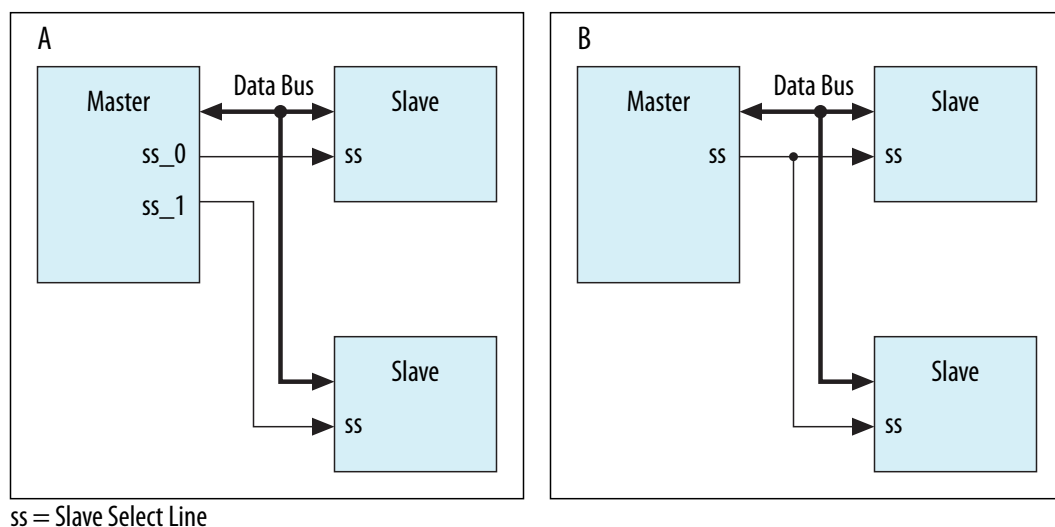

- Motorola SPI protocol – A four-wire, full-duplex serial protocol from Motorola. The slave select line is held high when the SPI controller is idle or disabled. For more information, refer to “Motorola SPI Protocol”. †
- Texas Instruments Serial Protocol (SSP) – A four-wire, full-duplex serial protocol. The slave select line used for SPI and Microwire protocols doubles as the frame indicator for the SSP protocol. For more information, refer to “Texas Instruments Synchronous Serial Protocol (SSP)”. †
- National Semiconductor Microwire – A half-duplex serial protocol, which uses a control word transmitted from the serial master to the target serial slave. For more information, refer to “National Semiconductor Microwire Protocol”. You can program the FRF (frame format) bit field in the Control Register 0 (CTRLR0) to select which protocol is used. †

The serial protocols supported by the SPI controller allow for serial slaves to be selected or addressed using hardware. Serial slaves are selected under the control of dedicated hardware select lines. The number of select lines generated from the serial master is equal to the number of serial slaves present on the bus. The serial-master device asserts the select line of the target serial slave before data transfer begins. This architecture is illustrated in part A of [Figure 140](#) on page 3986. †

When implemented in software, the input select line for all serial slave devices should originate from a single slave select output on the serial master. In this mode it is assumed that the serial master has only a single slave select output. If there are multiple serial masters in the system, the slave select output from all masters can be logically ANDed to generate a single slave select input for all serial slave devices. †

The main program in the software domain controls selection of the target slave device; this architecture is illustrated in part B of the [Figure 140](#) on page 3986 figure below. Software would control which slave is to respond to the serial transfer request from the master device. †

Figure 140. Hardware/Software Slave Selection

20.4.2.1. Serial Bit-Rate Clocks

20.4.2.1.1. SPI Master Bit-Rate Clock

The maximum frequency of the SPI master bit-rate clock (`sclk_out`) is one-half the frequency of SPI master clock (`l4_main_clk`). This allows the shift control logic to capture data on one clock edge of `sclk_out` and propagate data on the opposite edge. The `sclk_out` line toggles only when an active transfer is in progress. At all other times it is held in an inactive state, as defined by the serial protocol under which it operates. †

Figure 141. Maximum `sclk_out`/`l4_main_clk` Ratio

The frequency of `sclk_out` can be derived from the equation below, where $\langle \text{SPI clock} \rangle$ is `l4_main_clk` for both master and slave modules. †

$$F_{\text{sclk_out}} = F_{\langle \text{SPI clock} \rangle} / \text{SCKDV}$$

SCKDV is a bit field in the register `BAUDR`, holding any even value in the range 2 to 65,534. If SCKDV is 0, then `sclk_out` is disabled. †

The following equation describes the frequency ratio restrictions between the bit-rate clock `sclk_out` and the SPI master peripheral clock. The SPI master peripheral clock must be at least double the offchip master clock. †

Table 243. SPI Master Peripheral Clock

• SPI Master Peripheral Clock
$F_{l4_main_clk} \geq 2 \times (\text{maximum } F_{\text{sclk_out}})$ †

20.4.2.1.2. SPI Slave Bit-Rate Clock

The minimum frequency of `l4_main_clk` depends on the operation of the slave peripheral. If the slave device is *receive only*, the minimum frequency of `l4_main_clk` is six times the maximum expected frequency of the bit-rate clock from the master device (`sclk_in`). The `sclk_in` signal is double synchronized to the `l4_main_clk` domain, and then it is edge detected; this synchronization requires three `l4_main_clk` periods. †

If the slave device is *transmit and receive*, the minimum frequency of `l4_main_clk` is eight times the maximum expected frequency of the bit-rate clock from the master device (`sclk_in`). This ensures that data on the master `rx` line is stable before the master shift control logic captures the data. †

The frequency ratio restrictions between the bit-rate clock `sclk_in` and the SPI slave peripheral clock are as follows: †

- Slave (receive only): $F_{l4_main_clk} \geq 6 \times F_{sclk_in}$ (maximum F_{sclk_in}) †
- Slave: $F_{l4_main_clk} \geq 8 \times F_{sclk_in}$ (maximum F_{sclk_in}) †

20.4.2.2. Transmit and Receive FIFO Buffers

There are two 16-bit FIFO buffers, a transmit FIFO buffer and a receive FIFO buffer, with a depth of 256. Data frames that are less than 16 bits in size must be right-justified when written into the transmit FIFO buffer. The shift control logic automatically right-justifies receive data in the receive FIFO buffer. †

Each data entry in the FIFO buffers contains a single data frame. It is impossible to store multiple data frames in a single FIFO buffer location; for example, you may not store two 8-bit data frames in a single FIFO buffer location. If an 8-bit data frame is required, the upper 8-bits of the FIFO buffer entry are ignored or unused when the serial shifter transmits the data. †

The transmit and receive FIFO buffers are cleared when the SPI controller is disabled (`SSIENR=0`) or reset.

The transmit FIFO buffer is loaded by write commands to the SPI data register (`DR`). Data are popped (removed) from the transmit FIFO buffer by the shift control logic into the transmit shift register. The transmit FIFO buffer generates a transmit FIFO empty interrupt request when the number of entries in the FIFO buffer is less than or equal to the FIFO buffer threshold value. The threshold value, set through the register `TXFTLR`, determines the level of FIFO buffer entries at which an interrupt is generated. The threshold value allows you to provide early indication to the processor that the transmit FIFO buffer is nearly empty. A Transmit FIFO Overflow Interrupt is generated if you attempt to write data into an already full transmit FIFO buffer. †

Data are popped from the receive FIFO buffer by read commands to the SPI data register (`DR`). The receive FIFO buffer is loaded from the receive shift register by the shift control logic. The receive FIFO buffer generates a receive FIFO full interrupt request when the number of entries in the FIFO buffer is greater than or equal to the FIFO buffer threshold value plus one. The threshold value, set through register `RXFTLR`, determines the level of FIFO buffer entries at which an interrupt is generated. †

The threshold value allows you to provide early indication to the processor that the receive FIFO buffer is nearly full. A Receive FIFO Overrun Interrupt is generated when the receive shift logic attempts to load data into a completely full receive FIFO buffer. However, the newly received data are lost. A Receive FIFO Underflow Interrupt is generated if you attempt to read from an empty receive FIFO buffer. This alerts the processor that the read data are invalid. †

Related Information

[Reset Manager](#) on page 138

For more information, refer to the *Reset Manager* chapter.

20.4.2.3. SPI Interrupts

The SPI controller supports combined interrupt requests, which can be masked. The combined interrupt request is the ORed result of all other SPI interrupts after masking. All SPI interrupts have active-high polarity level. The SPI interrupts are described as follows: †

- Transmit FIFO Empty Interrupt – Set when the transmit FIFO buffer is equal to or below its threshold value and requires service to prevent an underrun. The threshold value, set through a software-programmable register, determines the level of transmit FIFO buffer entries at which an interrupt is generated. This interrupt is cleared by hardware when data are written into the transmit FIFO buffer, bringing it over the threshold level. †
- Transmit FIFO Overflow Interrupt – Set when a master attempts to write data into the transmit FIFO buffer after it has been completely filled. When set, new data writes are discarded. This interrupt remains set until you read the transmit FIFO overflow interrupt clear register (TXOICR). †
- Receive FIFO Full Interrupt – Set when the receive FIFO buffer is equal to or above its threshold value plus 1 and requires service to prevent an overflow. The threshold value, set through a software-programmable register, determines the level of receive FIFO buffer entries at which an interrupt is generated. This interrupt is cleared by hardware when data are read from the receive FIFO buffer, bringing it below the threshold level. †
- Receive FIFO Overflow Interrupt – Set when the receive logic attempts to place data into the receive FIFO buffer after it has been completely filled. When set, newly received data are discarded. This interrupt remains set until you read the receive FIFO overflow interrupt clear register (RXOICR). †
- Receive FIFO Underflow Interrupt – Set when a system bus access attempts to read from the receive FIFO buffer when it is empty. When set, zeros are read back from the receive FIFO buffer. This interrupt remains set until you read the receive FIFO underflow interrupt clear register (RXUICR). †
- Combined Interrupt Request – ORed result of all the above interrupt requests after masking. To mask this interrupt signal, you must mask all other SPI interrupt requests. †

Transmit FIFO Overflow, Transmit FIFO Empty, Receive FIFO Full, Receive FIFO Underflow, and Receive FIFO Overflow interrupts can all be masked independently, using the Interrupt Mask Register (IMR). †

20.4.3. Transfer Modes

When transferring data on the serial bus, the SPI controller operates one of several modes. The transfer mode (TMOD) is set by writing to the TMOD field in control register 0 (CTRLR0).

Note: The transfer mode setting does not affect the duplex of the serial transfer. TMOD is ignored for Microwire transfers, which are controlled by the MWCR register. †

20.4.3.1. Transmit and Receive

When TMOD = 0, both transmit and receive logic are valid. The data transfer occurs as normal according to the selected frame format (serial protocol). Transmit data are popped from the transmit FIFO buffer and sent through the `txd` line to the target

device, which replies with data on the `rx` line. The receive data from the target device is moved from the receive shift register into the receive FIFO buffer at the end of each data frame. †

20.4.3.2. Transmit Only

When `TMOD = 1`, any receive data are ignored. The data transfer occurs as normal, according to the selected frame format (serial protocol). Transmit data are popped from the transmit FIFO buffer and sent through the `tx` line to the target device, which replies with data on the `rx` line. At the end of the data frame, the receive shift register does not load its newly received data into the receive FIFO buffer. The data in the receive shift register is overwritten by the next transfer. You should mask interrupts originating from the receive logic when this mode is entered. †

20.4.3.3. Receive Only

When `TMOD = 2`, the transmit data are invalid. In the case of the SPI slave, the transmit FIFO buffer is never popped in Receive Only mode. The `tx` output remains at a constant logic level during the transmission. The data transfer occurs as normal according to the selected frame format (serial protocol). The receive data from the target device is moved from the receive shift register into the receive FIFO buffer at the end of each data frame. You should mask interrupts originating from the transmit logic when this mode is entered. †

20.4.3.4. EEPROM Read

Note: This transfer mode is only valid for serial masters. †

When `TMOD = 3`, the transmit data is used to transmit an opcode and/or an address to the EEPROM device. This takes three data frames (8-bit opcode followed by 8-bit upper address and 8-bit lower address). During the transmission of the opcode and address, no data is captured by the receive logic (as long as the SPI master is transmitting data on its `tx` line, data on the `rx` line is ignored). The SPI master continues to transmit data until the transmit FIFO buffer is empty. You should ONLY have enough data frames in the transmit FIFO buffer to supply the opcode and address to the EEPROM. If more data frames are in the transmit FIFO buffer than are needed, then Read data is lost. †

When the transmit FIFO buffer becomes empty (all control information has been sent), data on the receive line (`rx`) is valid and is stored in the receive FIFO buffer; the `tx` output is held at a constant logic level. The serial transfer continues until the number of data frames received by the SPI master matches the value of the `NDF` field in the `CTRLR1` register plus one. †

Note: EEPROM read mode is not supported when the SPI controller is configured to be in the SSP mode. †

20.4.4. SPI Master

The SPI master initiates and controls all serial transfers with serial-slave peripheral devices. †

The serial bit-rate clock, generated and controlled by the SPI controller, is driven out on the `sclk_out` line. When the SPI controller is disabled, no serial transfers can occur and `sclk_out` is held in "inactive" state, as defined by the serial protocol under which it operates. †

Related Information

[SPI Block Diagram](#) on page 3983

20.4.4.1. RXD Sample Delay

The SPI master device is capable of delaying the default sample time of the `rx_d` signal in order to increase the maximum achievable frequency on the serial bus.

Round trip routing delays on the `sclk_out` signal from the master and the `rx_d` signal from the slave can mean that the timing of the `rx_d` signal, as seen by the master, has moved away from the normal sampling time.

Without the RXD sample delay, you must increase the baud rate for the transfer in order to ensure that the setup times on the `rx_d` signal are within range. This reduces the frequency of the serial interface.

Additional logic is included in the SPI master to delay the default sample time of the `rx_d` signal. This additional logic can help to increase the maximum achievable frequency on the serial bus. †

By writing to the `rsd` field of the RXD sample delay register (`rx_sample_dly`), you specify an additional amount of delay applied to the `rx_d` sample. The delay is in number of `l4_main_clk` clock cycles, with 64 maximum cycles allowed (zero is reserved). If the `rsd` field is programmed with a value exceeding 64, a zero delay is applied to the `rx_d` sample.

The sample delay logic has a resolution of one `l4_main_clk` cycle. Software can "train" the serial bus by coding a loop that continually reads from the slave and increments the master's RXD sample delay value until the correct data is received by the master. †

Figure 142. Effects of Round Trip Routing Delays on sclk_out Signal

20.4.4.2. Data Transfers

The SPI master starts data transfers when all the following conditions are met:

- The SPI master is enabled
- There is at least one valid entry in the transmit FIFO buffer
- A slave device is selected

When actively transferring data, the busy flag (`BUSY`) in the status register (`SR`) is set. You must wait until the busy flag is cleared before attempting a new serial transfer. †

Note:

The `BUSY` status is not set when the data are written into the transmit FIFO buffer. This bit gets set only when the target slave has been selected and the transfer is underway. After writing data into the transmit FIFO buffer, the shift logic does not begin the serial transfer until a positive edge of the `sclk_out` signal is present. The delay in waiting for this positive edge depends on the baud rate of the serial transfer. Before polling the `BUSY` status, you should first poll the Transmit FIFO Empty (`TFE`) status (waiting for 1) or wait for $(\text{BAUDR} * \text{SPI clock})$ clock cycles. †

20.4.4.3. Master SPI and SSP Serial Transfers

“Motorola SPI Protocol” and “Texas Instruments Synchronous Serial Protocol (SSP)” describe the SPI and SSP serial protocols, respectively. †

When the transfer mode is “transmit and receive” or “transmit only” (`TMOD = 0` or `TMOD = 1`, respectively), transfers are terminated by the shift control logic when the transmit FIFO buffer is empty. For continuous data transfers, you must ensure that the transmit FIFO buffer does not become empty before all the data have been transmitted. The transmit FIFO threshold level (`TXFTLR`) can be used to early interrupt (Transmit FIFO Empty Interrupt) the processor indicating that the transmit FIFO buffer is nearly empty. †

When the DMA is used in conjunction with the SPI master, the transmit data level (DMATDLR) can be used to early request the DMA Controller, indicating that the transmit FIFO buffer is nearly empty. The FIFO buffer can then be refilled with data to continue the serial transfer. The user may also write a block of data (at least two FIFO buffer entries) into the transmit FIFO buffer before enabling a serial slave. This ensures that serial transmission does not begin until the number of data frames that make up the continuous transfer are present in the transmit FIFO buffer. †

When the transfer mode is “receive only” (TMOD = 2), a serial transfer is started by writing one “dummy” data word into the transmit FIFO buffer when a serial slave is selected. The `txd` output from the SPI controller is held at a constant logic level for the duration of the serial transfer. The transmit FIFO buffer is popped only once at the beginning and may remain empty for the duration of the serial transfer. The end of the serial transfer is controlled by the “number of data frames” (NDF) field in control register 1 (CTRLR1). †

If, for example, you want to receive 24 data frames from a serial-slave peripheral, you should program the NDF field with the value 23; the receive logic terminates the serial transfer when the number of frames received is equal to the NDF value plus one. This transfer mode increases the bandwidth of the system bus as the transmit FIFO buffer never needs to be serviced during the transfer. The receive FIFO buffer should be read each time the receive FIFO buffer generates a FIFO full interrupt request to prevent an overflow. †

When the transfer mode is “eeprom_read” (TMOD = 3), a serial transfer is started by writing the opcode and/or address into the transmit FIFO buffer when a serial slave (EEPROM) is selected. The opcode and address are transmitted to the EEPROM device, after which read data is received from the EEPROM device and stored in the receive FIFO buffer. The end of the serial transfer is controlled by the NDF field in the control register 1 (CTRLR1). †

Note: EEPROM read mode is not supported when the SPI controller is configured to be in the SSP mode. †

The receive FIFO threshold level (RXFTLR) can be used to give early indication that the receive FIFO buffer is nearly full. When a DMA is used, the receive data level (DMARDLR) can be used to early request the DMA Controller, indicating that the receive FIFO buffer is nearly full. †

20.4.4.4. Master Microwire Serial Transfers

“National Semiconductor Microwire Protocol” describes the Microwire serial protocol in detail. †

Microwire serial transfers from the SPI serial master are controlled by the Microwire Control Register (MWCR). The MHS bit field enables and disables the Microwire handshaking interface. The MDD bit field controls the direction of the data frame (the control frame is always transmitted by the master and received by the slave). The MWMOD bit field defines whether the transfer is sequential or nonsequential. †

All Microwire transfers are started by the SPI serial master when there is at least one control word in the transmit FIFO buffer and a slave is enabled. When the SPI master transmits the data frame ($MDD = 1$), the transfer is terminated by the shift logic when the transmit FIFO buffer is empty. When the SPI master receives the data frame ($MDD = 1$), the termination of the transfer depends on the setting of the $MWMOD$ bit field. If the transfer is nonsequential ($MWMOD = 0$), it is terminated when the transmit FIFO buffer is empty after shifting in the data frame from the slave. When the transfer is sequential ($MWMOD = 1$), it is terminated by the shift logic when the number of data frames received is equal to the value in the $CTRLR1$ register plus one. †

When the handshaking interface on the SPI master is enabled ($MHS = 1$), the status of the target slave is polled after transmission. Only when the slave reports a *ready status* does the SPI master complete the transfer and clear its *BUSY* status. If the transfer is continuous, the next control/data frame is not sent until the slave device returns a *ready status*. †

Related Information

National Semiconductor Microwire Protocol on page 4001

20.4.5. SPI Slave

The SPI slave handles serial communication with transfer initiated and controlled by serial master peripheral devices.

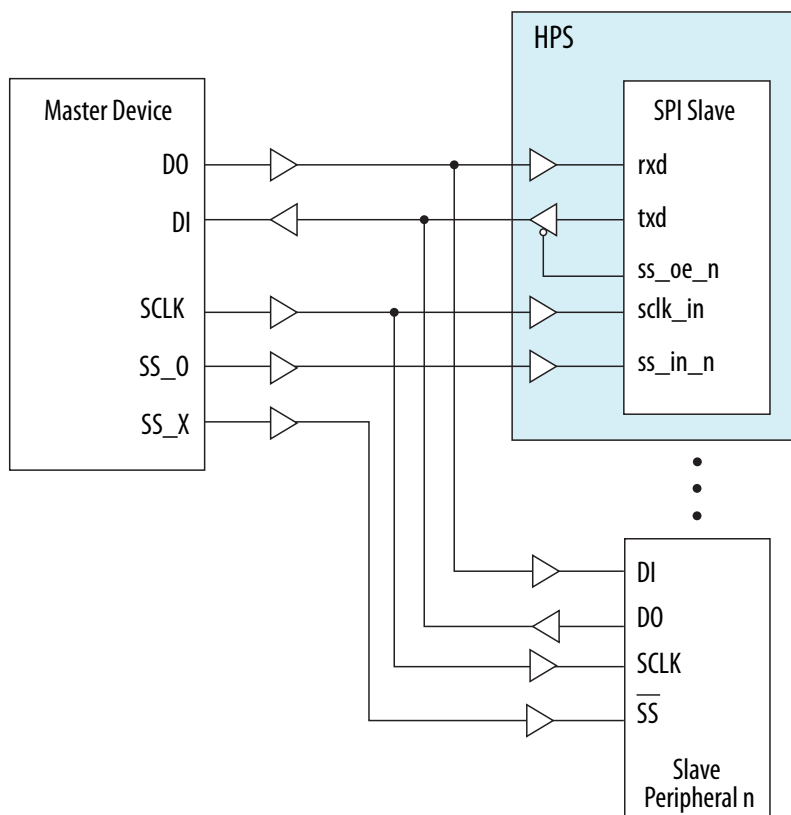

- `sclk_in`—serial clock to the SPI slave †
- `ss_in_n`—slave select input to the SPI slave †
- `ss_oe_n`—output enable for the SPI master or slave †
- `txd`—transmit data line for the SPI master or slave †
- `rxn`—receive data line for the SPI master or slave †

When the SPI serial slave is selected, it enables its `txd` data onto the serial bus. All data transfers to and from the serial slave are regulated on the serial clock line (`sclk_in`), driven from the SPI master device. Data are propagated from the serial slave on one edge of the serial clock line and sampled on the opposite edge. †

When the SPI serial slave is not selected, it must not interfere with data transfers between the serial-master and other serial-slave devices. When the serial slave is not selected, its `txd` output is buffered, resulting in a high impedance drive onto the SPI master `rxn` line. The buffers shown in the [Figure 143](#) on page 3995 figure are external to the SPI controller. `spi_oe_n` is the SPI slave output enable signal. †

The serial clock that regulates the data transfer is generated by the serial-master device and input to the SPI slave on `sclk_in`. The slave remains in an idle state until selected by the bus master. When not actively transmitting data, the slave must hold its `txd` line in a high impedance state to avoid interference with serial transfers to other slave devices. The SPI slave output enable (`ss_oe_n`) signal is available for use to control the `txd` output buffer. The slave continues to transfer data to and from the master device as long as it is selected. If the master transmits to all serial slaves, a control bit (`SLV_OE`) in the SPI control register 0 (`CTRLR0`) can be programmed to inform the slave if it should respond with data from its `txd` line. †

Figure 143. SPI Slave

The `slv_oe` bit in the control register is only valid if the SPI slave interface is routed to the FPGA. To use the SPI slave in a multi master system or in a system that requires the SPI slave TXD to be tri-stated, you can do the following:

- If you want the SPI slave to control the tri-state of TXD, it must be routed to the FPGA first and use the FPGA IO. HPS I/O can also be used via the Loan I/O interface (timing permitting).
- If you do not want to route to the FPGA, then software control of the TXD (tri-state) must be performed with the already included code to control via an HPS GPIO input. Please refer to the pin connection guidelines to find which GPIO pins correspond to which HPS SPI slave SS ports.

20.4.5.1. Slave SPI and SSP Serial Transfers

“Motorola SPI Protocol” and the “Texas Instruments Synchronous Serial Protocol (SSP)” contain a description of the SPI and SSP serial protocols, respectively. †

If the SPI slave is *receive only* (TMOD=2), the transmit FIFO buffer need not contain valid data because the data currently in the transmit shift register is resent each time the slave device is selected. The TXE error flag in the status register (SR) is not set when TMOD=2. You should mask the Transmit FIFO Empty Interrupt when this mode is used. †

If the SPI slave transmits data to the master, you must ensure that data exists in the transmit FIFO buffer before a transfer is initiated by the serial-master device. If the master initiates a transfer to the SPI slave when no data exists in the transmit FIFO buffer, an error flag (TXE) is set in the SPI status register, and the previously transmitted data frame is resent on `txd`. For continuous data transfers, you must ensure that the transmit FIFO buffer does not become empty before all the data have been transmitted. The transmit FIFO threshold level register (TXFTLR) can be used to early interrupt (Transmit FIFO Empty Interrupt) the processor, indicating that the transmit FIFO buffer is nearly empty. When a DMA Controller is used, the DMA transmit data level register (DMATDLR) can be used to early request the DMA Controller, indicating that the transmit FIFO buffer is nearly empty. The FIFO buffer can then be refilled with data to continue the serial transfer. †

The receive FIFO buffer should be read each time the receive FIFO buffer generates a FIFO full interrupt request to prevent an overflow. The receive FIFO threshold level register (RXFTLR) can be used to give early indication that the receive FIFO buffer is nearly full. When a DMA Controller is used, the DMA receive data level register (DMARDLR) can be used to early request the DMA controller, indicating that the receive FIFO buffer is nearly full. †

20.4.5.2. Serial Transfers

“National Semiconductor Microwire Protocol” describes the Microwire serial protocol in detail, including timing diagrams and information about how data are structured in the transmit and receive FIFO buffers before and after a serial transfer. The Microwire protocol operates in much the same way as the SPI protocol. There is no decode of the control frame by the SPI slave device. †

Related Information

[National Semiconductor Microwire Protocol](#) on page 4001

20.4.5.3. Glue Logic for Master Port `ss_in_n`

When configured as a master, the SPI has an input, `ssi_in_n`, which can be used by the deciding logic in a multi-master system to disable one master when another has priority. The polarity of this signal depends on the serial protocol in use, and the protocol is dynamically selectable.

The table below lists the three protocols and the effect of `ss_in_n` on the ability of the master to transfer data. Note that for the SSP protocol the effect of `ss_in_n` is inverted with respect to the other protocols.

Protocol	<code>ss_in_n</code> value	Effect on Serial Transfer
Motorola SPI	1	Enabled
	0	Disabled
National Semiconductor Microwire	1	Enabled
	0	Disabled
Texas Instruments Serial Protocol (SSP)	1	Disabled
	0	Enabled

Figure 144. Arbitration Between Multiple Serial Masters

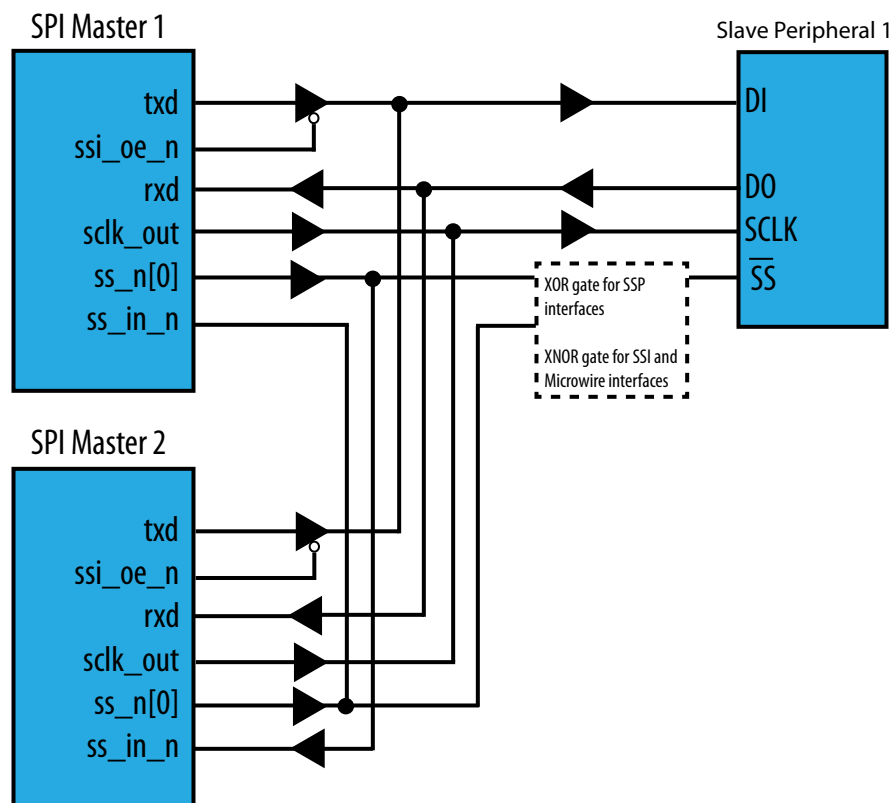

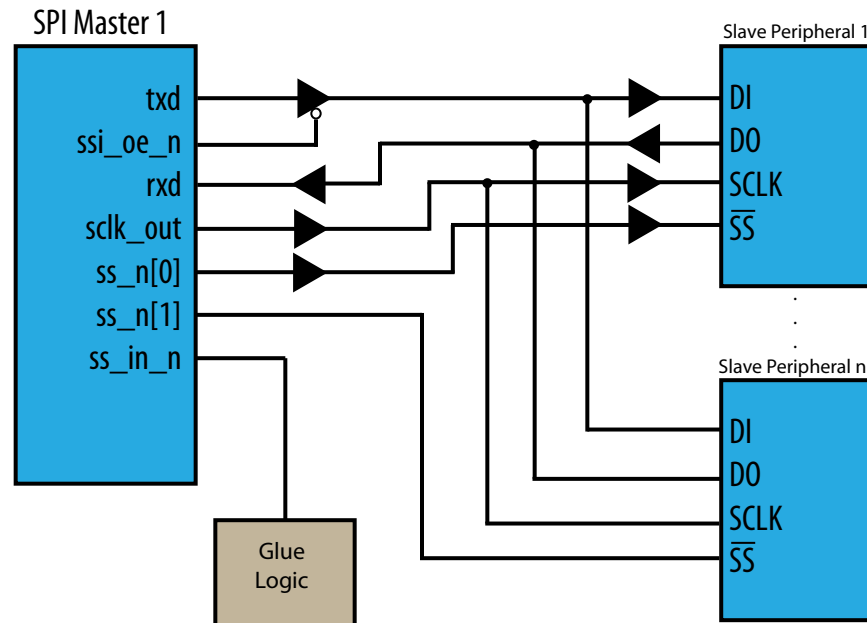

Figure 145. SPI Configured as Master Device

20.4.6. Partner Connection Interfaces

The SPI can connect to any serial-master or serial-slave peripheral device using one of several interfaces.

20.4.6.1. Motorola SPI Protocol

With SPI, the clock polarity (SCPOL) configuration parameter determines whether the inactive state of the serial clock is high or low. The data frame can be 4 to 16 bits in length. †

When the configuration parameter (SCPH = 0), data transmission begins on the falling edge of the slave select signal. The first data bit is captured by the master and slave peripherals on the first edge of the serial clock; therefore, valid data must be present on the `txd` and `rxd` lines prior to the first serial clock edge. †

The slave select signal takes effect only when used as slave SPI. For master SPI, the data transmission begins as soon as the output enable signal is deasserted.

The following signals are illustrated in the timing diagrams in this section: †

- `sclk_out`—serial clock from SPI master †
- `sclk_in`—serial clock from SPI slave †
- `ss_0_n`—slave select signal from SPI master †
- `ss_oe_n`—output enable for the SPI master or slave †
- `txd`—transmit data line for the SPI master or slave †
- `rxn`—receive data line for the SPI master or slave †

Figure 146. SPI Serial Format (SCPH = 0)

There are four possible transfer modes on the SPI controller for performing SPI serial transactions; refer to “Transfer Modes” . For *transmit and receive transfers* (transfer mode field (9:8) of the Control Register 0 = 0), data transmitted from the SPI controller to the external serial device is written into the transmit FIFO buffer. Data received from the external serial device into the SPI controller is pushed into the receive FIFO buffer. †

Note: For *transmit only* transfers (transfer mode field (9:8) of the Control Register 0 = 1), data transmitted from the SPI controller to the external serial device is written into the transmit FIFO buffer. As the data received from the external serial device is deemed invalid, it is not stored in the SPI receive FIFO buffer. †

For *receive only* transfers (transfer mode field (9:8) of the Control Register 0 = 2), data transmitted from the SPI controller to the external serial device is invalid, so a single dummy word is written into the transmit FIFO buffer to begin the serial transfer. The `txd` output from the SPI controller is held at a constant logic level for the duration of the serial transfer. Data received from the external serial device into the SPI controller is pushed into the receive FIFO buffer. †

For EEPROM read transfers (transfer mode field [9:8] of the Control Register 0 = 3), opcode and/or EEPROM address are written into the transmit FIFO buffer. During transmission of these control frames, received data is not captured by the SPI master. After the control frames have been transmitted, receive data from the EEPROM is stored in the receive FIFO buffer.

SPI Serial Format

Two different modes of continuous data transfers are supported when $SCPH = 0$ and 1.[†]

- When clock phase $SCPH = 0$, the SPI Controller deasserts the slave select signal between each data word and the serial clock is held to its default value while the slave select signal is deasserted.[†]
- When $SCPH = 1$, the slave select is held asserted (active low) for the duration of the transfer.[†]

Figure 147. Serial Format Continuous Transfers ($SCPH = 0$)

Figure 148. Serial Format Continuous Transfers ($SCPH = 1$)

Related Information

[Transfer Modes](#) on page 3989

20.4.6.2. Texas Instruments Synchronous Serial Protocol (SSP)

Data transfers begin by asserting the frame indicator line (ss_0_n) for one serial clock period. Data to be transmitted are driven onto the txd line one serial clock cycle later; similarly data from the slave are driven onto the rxn line. Data are propagated on the rising edge of the serial clock ($sclk_out/sclk_in$) and captured on the falling edge. The length of the data frame ranges from 4 to 16 bits.

Note: The slave select signal (*ss_0_n*) takes effect only when used as slave SPI. For master SPI, the data transmission begins as soon as the output enable signal is deasserted.

Figure 149. SSP Serial Format

Continuous data frames are transferred in the same way as single data frames. The frame indicator is asserted for one clock period during the same cycle as the LSB from the current transfer, indicating that another data frame follows. †

Figure 150. SSP Serial Format Continuous Transfer

20.4.6.3. National Semiconductor Microwire Protocol

For the master SPI, data transmission begins as soon as the output enable signal is deasserted. One-half serial clock (*sclk_out*) period later, the first bit of the control is sent out on the *txd* line. The length of the control word can be in the range 1 to 16 bits and is set by writing bit field CFS (bits 15:12) in *CTRLR0*. The remainder of the control word is transmitted (propagated on the falling edge of *sclk_out*) by the SPI serial master. During this transmission, no data are present (high impedance) on the serial master's *rx*d line. †

The direction of the data word is controlled by the *MDD* bit field (bit 1) in the Microwire Control Register (*MWCR*). When *MDD*=0, this indicates that the SPI serial master receives data from the external serial slave. One clock cycle after the LSB of the control word is transmitted, the slave peripheral responds with a dummy 0 bit, followed by the data frame, which can be 4 to 16 bits in length. Data are propagated on the falling edge of the serial clock and captured on the rising edge. †

Continuous transfers from the Microwire protocol can be sequential or nonsequential, and are controlled by the *MWMOD* bit field (bit 0) in the *MWCR*. †

Nonsequential continuous transfers occur, with the control word for the next transfer following immediately after the LSB of the current data word. †

The only modification needed to perform a continuous nonsequential transfer is to write more control words into the transmit FIFO buffer. †

During sequential continuous transfers, only one control word is transmitted from the SPI master. The transfer is started in the same manner as with nonsequential read operations, but the cycle is continued to read further data. The slave device automatically increments its address pointer to the next location and continues to provide data from that location. Any number of locations can be read in this manner; the SPI master terminates the transfer when the number of words received is equal to the value in the `CTRLR1` register plus one. †

When `MDD = 1`, this indicates that the SPI serial master transmits data to the external serial slave. Immediately after the LSB of the control word is transmitted, the SPI master begins transmitting the data frame to the slave peripheral. †

Note: The SPI controller does not support continuous sequential Microwire writes, where `MDD = 1` and `MWMOD = 1`. †

Continuous transfers occur with the control word for the next transfer following immediately after the LSB of the current data word.

The Microwire handshaking interface can also be enabled for SPI master write operations to external serial-slave devices. To enable the handshaking interface, you must write 1 into the `MHS` bit field (bit 2) on the `MWCR` register. When `MHS` is set to 1, the SPI serial master checks for a ready status from the slave device before completing the transfer, or transmitting the next control word for continuous transfers. †

After the first data word has been transmitted to the serial-slave device, the SPI master polls the `rx_d` input waiting for a ready status from the slave device. Upon reception of the ready status, the SPI master begins transmission of the next control word. After transmission of the last data frame has completed, the SPI master transmits a start bit to clear the ready status of the slave device before completing the transfer. †

In the SPI slave, data transmission begins with the falling edge of the slave select signal (`ss_in_0`). One-half serial clock (`sclk_in`) period later, the first bit of the control is present on the `rx_d` line. The length of the control word can be in the range of 1 to 16 bits and is set by writing bit field `CFS` in the `CTRLR0` register. The `CFS` bit field must be set to the size of the expected control word from the serial master. The remainder of the control word is received (captured on the rising edge of `sclk_in`) by the SPI serial slave. During this reception, no data are driven (high impedance) on the serial slave's `tx_d` line. †

The direction of the data word is controlled by the `MDD` bit field (bit 1) `MWCR` register. When `MDD=0`, this indicates that the SPI serial slave is to receive data from the external serial master. Immediately after the control word is transmitted, the serial master begins to drive the data frame onto the SPI slave `rx_d` line. Data are propagated on the falling edge of the serial clock and captured on the rising edge. The slave-select signal is held active-low during the transfer and is deasserted one-half clock cycle later after the data are transferred. The SPI slave output enable signal is held inactive for the duration of the transfer. †

When `MDD=1`, this indicates that the SPI serial slave transmits data to the external serial master. Immediately after the LSB of the control word is transmitted, the SPI slave transmits a dummy 0 bit, followed by the 4- to 16-bit data frame on the `tx_d` line. †

Continuous transfers for a SPI slave occur in the same way as those specified for the SPI master. The SPI slave does not support the handshaking interface, as there is never a busy period. †

Figure 151. Single SPI Serial Master Microwire Serial Transfer (MDD=0)

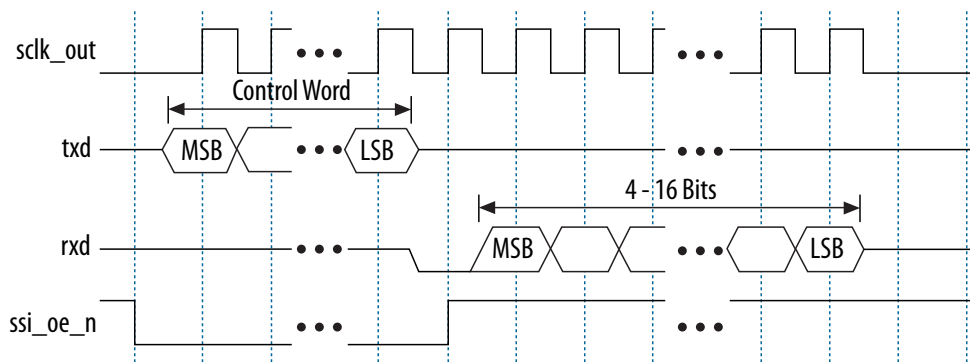

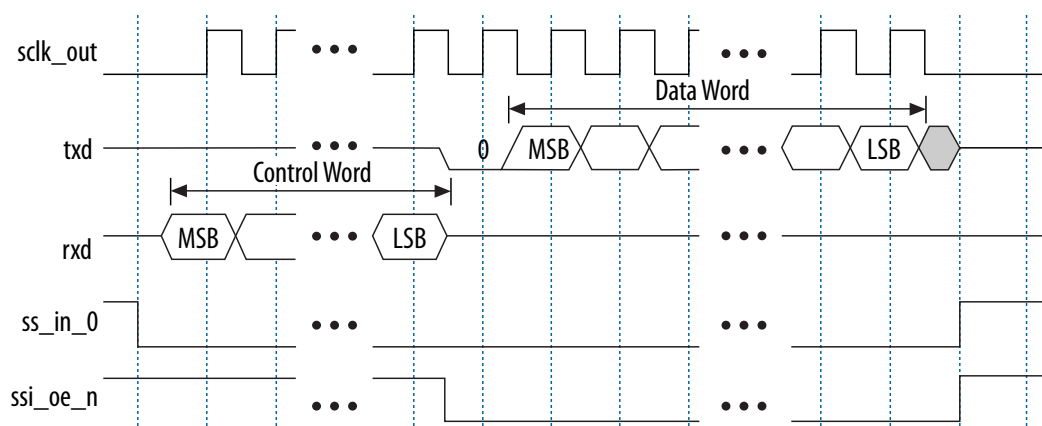

Figure 152. Single SPI Slave Microwire Serial Transfer (MDD=1)

20.4.7. DMA Controller Interface

The SPI controller supports DMA signaling to indicate when the receive FIFO buffer has data ready to be read or when the transmit FIFO buffer needs data. It requires two DMA channels, one for transmit data and one for receive data. The SPI controller can issue single or burst DMA transfers and accepts burst acknowledges from the DMA. System software can trigger the DMA burst mode by programming an appropriate value into the threshold registers. The typical setting of the threshold register value is half full.

To enable the DMA Controller interface on the SPI controller, you must write the DMA Control Register (DMACR). Writing a 1 into the TDMAE bit field of DMACR register enables the SPI transmit handshaking interface. Writing a 1 into the RDMAE bit field of the DMACR register enables the SPI receive handshaking interface. †

20.4.8. Slave Interface

The host processor accesses data, control, and status information about the SPI controller through the slave interface. The SPI supports a data bus width of 32 bits.

20.4.8.1. Control and Status Register Access

Control and status registers within the SPI controller are byte-addressable. The maximum width of the control or status register in the SPI controller is 16 bits. Therefore, all read and write operations to the SPI control and status registers require only one access. †

20.4.8.2. Data Register Access

The data register (DR) within the SPI controller is 16 bits wide in order to remain consistent with the maximum serial transfer size (data frame). A write operation to DR moves data from the slave write data bus into the transmit FIFO buffer. An read operation from DR moves data from the receive FIFO buffer onto the slave readback data bus. †

Note: The DR register in the SPI controller occupies sixty-four 32-bit locations of the memory map to facilitate burst transfers. There are no burst transactions on the system bus itself, but SPI supports bursts on the system interconnect. Writing to any of these address locations has the same effect as pushing the data from the slave write data bus into the transmit FIFO buffer. Reading from any of these locations has the same effect as popping data from the receive FIFO buffer onto the slave readback data bus. The FIFO buffers on the SPI controller are not addressable.

20.4.9. Clocks and Resets

The SPI controller uses the clock and reset signals shown in the following table.

Table 244. SPI Controller Clocks and Resets

	Master	Slave
SPI clock	l4_main_clk	l4_main_clk
SPI bit-rate clock	sclk_out	sclk_in
Reset	spim_rst_n	spis_rst_n

20.4.9.1. Clock Gating

You can locally clock gate the l4_main_clk to the Master SPI by programming the spimclken bit of the en register in the perpllgroup.

Note: This option is not available for SPI slaves.

Related Information

[Clock Manager Address Map and Register Definitions](#) on page 71

20.4.9.2. Taking the SPI Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

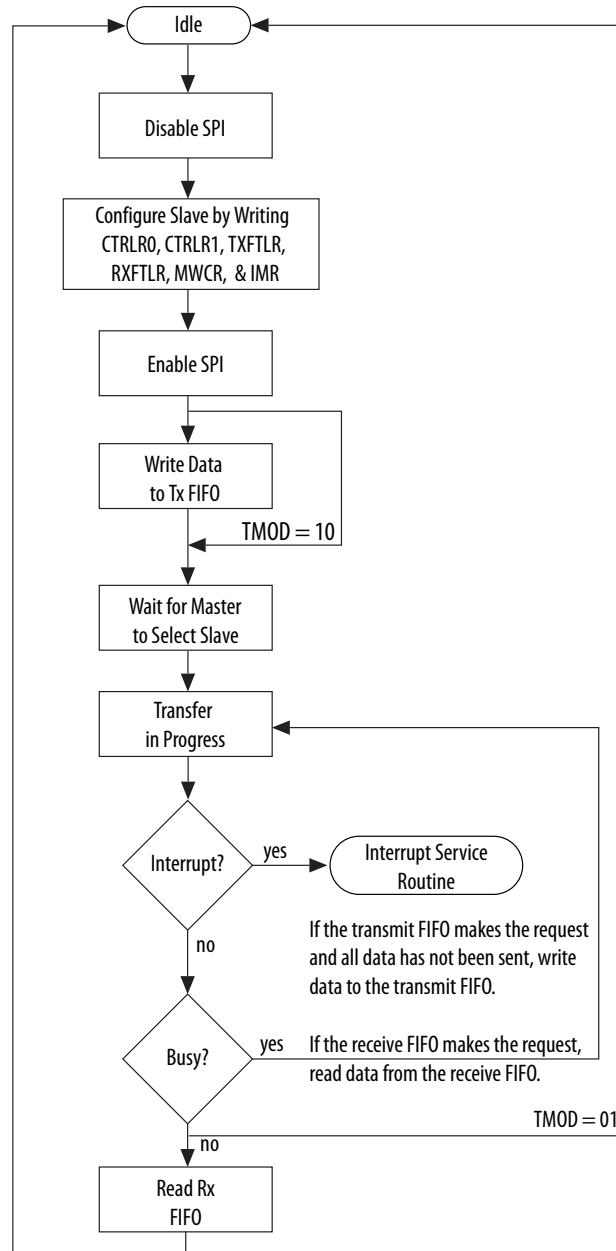

20.5. SPI Programming Model

This section describes the programming model for the SPI controller, for the following master and slave transfer types:

- Master SPI and SSP serial transfers
- Master Microwire serial transfers
- Slave SPI and SSP serial transfers
- Slave Microwire serial transfers
- Software Control for slave selection

20.5.1. Master SPI and SSP Serial Transfers

Figure 153. Master SPI or SSP Serial Transfer Software Flow

To complete an SPI or SSP serial transfer from the SPI master, follow these steps:

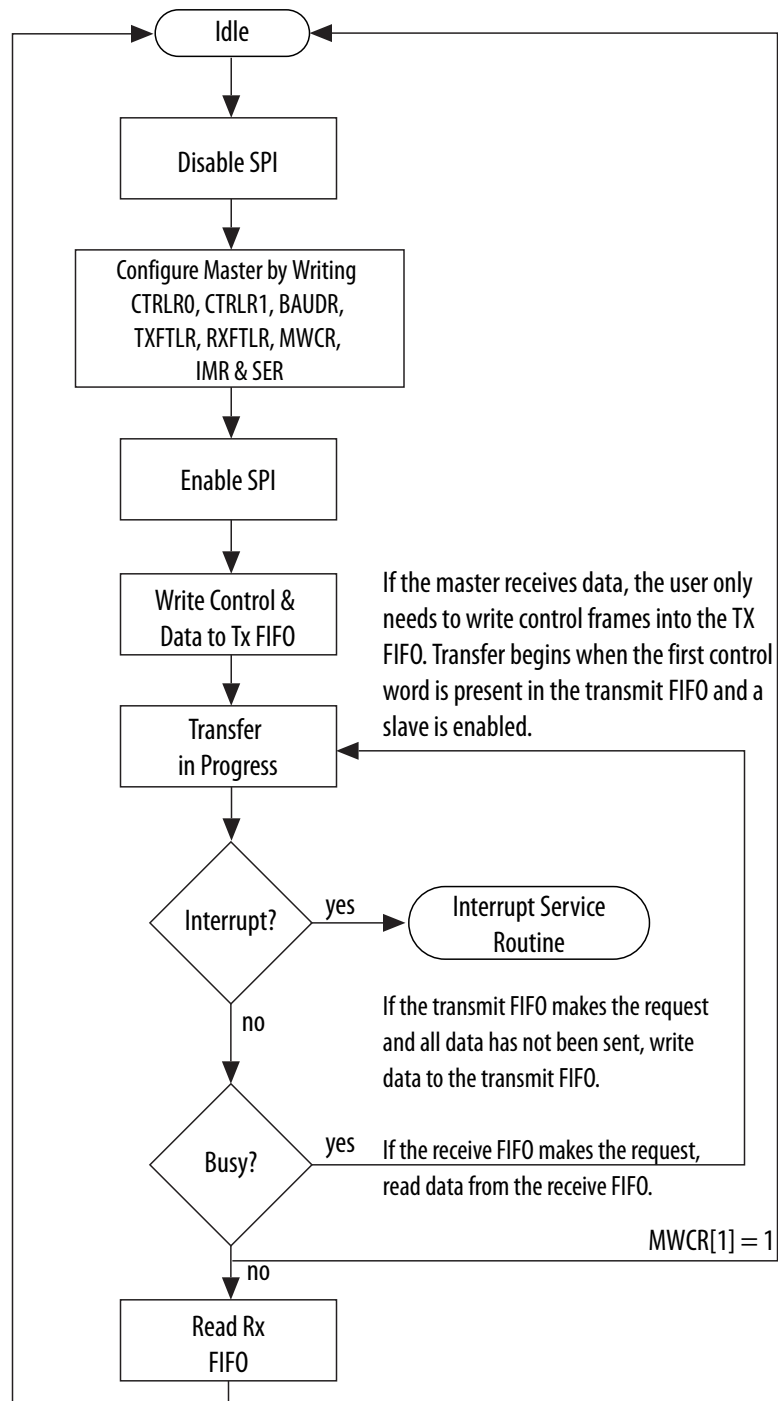

1. If the SPI master is enabled, disable it by writing 0 to the SSI Enable register (SSIENR).
2. Set up the SPI master control registers for the transfer. You can set these registers in any order.

- Write Control Register 0 (CTRLR0). For SPI transfers, you must set the serial clock polarity and serial clock phase parameters identical to the target slave device.
 - If the transfer mode is receive only, write Control Register 1 (CTRLR1) with the number of frames in the transfer minus 1. For example, if you want to receive four data frames, write 3 to this register.
 - Write the Baud Rate Select Register (BAUDR) to set the baud rate for the transfer.
 - Write the Transmit and Receive FIFO Threshold Level registers (TXFTLR and RXFTLR) to set FIFO buffer threshold levels.
 - Write the IMR register to set up interrupt masks.
 - Write the Slave Enable Register (SER) register to enable the target slave for selection. If a slave is enabled at this time, the transfer begins as soon as one valid data entry is present in the transmit FIFO buffer. If no slaves are enabled prior to writing to the Data Register (DR), the transfer does not begin until a slave is enabled.
3. Enable the SPI master by writing 1 to the SSIENR register.
 4. Write data for transmission to the target slave into the transmit FIFO buffer (write DR). If no slaves were enabled in the SER register at this point, enable it now to begin the transfer.
 5. Poll the BUSY status to wait for the transfer to complete. If a transmit FIFO empty interrupt request is made, write the transmit FIFO buffer (write DR). If a receive FIFO full interrupt request is made, read the receive FIFO buffer (read DR).
 6. The shift control logic stops the transfer when the transmit FIFO buffer is empty. If the transfer mode is receive only (TMOD = 2), the shift control logic stops the transfer when the specified number of frames have been received. When the transfer is done, the BUSY status is reset to 0.
 7. If the transfer mode is not transmit only (TMOD is not equal to 1), read the receive FIFO buffer until it is empty
 8. Disable the SPI master by writing 0 to SSIENR.

20.5.2. Master Microwire Serial Transfers

Figure 154. Microwire Serial

To complete a Microwire serial transfer from the SPI master, follow these steps:

1. If the SPI master is enabled, disable it by writing 0 to `SSIENR`.
2. Set up the SPI control registers for the transfer. You can set these registers in any order.
 - Write `CTRLR0` to set transfer parameters. If the transfer is sequential and the SPI master receives data, write `CTRLR1` with the number of frames in the transfer minus 1. For example, if you want to receive four data frames, write 3 to this register.
 - Write `BAUDR` to set the baud rate for the transfer.
 - Write `TXFTLR` and `RXFTLR` to set FIFO buffer threshold levels.
 - Write the `IMR` register to set up interrupt masks.

You can write the `SER` register to enable the target slave for selection. If a slave is enabled here, the transfer begins as soon as one valid data entry is present in the transmit FIFO buffer. If no slaves are enabled prior to writing to the `DR` register, the transfer does not begin until a slave is enabled.

3. Enable the SPI master by writing 1 to the `SSIENR` register.
4. If the SPI master transmits data, write the control and data words into the transmit FIFO buffer (write `DR`). If the SPI master receives data, write the control word or words into the transmit FIFO buffer. If no slaves were enabled in the `SER` register at this point, enable now to begin the transfer.
5. Poll the `BUSY` status to wait for the transfer to complete. If a transmit FIFO empty interrupt request is made, write the transmit FIFO buffer (write `DR`). If a receive FIFO full interrupt request is made, read the receive FIFO buffer (read `DR`).
6. The shift control logic stops the transfer when the transmit FIFO buffer is empty. If the transfer mode is sequential and the SPI master receives data, the shift control logic stops the transfer when the specified number of data frames is received. When the transfer is done, the `BUSY` status is reset to 0.
7. If the SPI master receives data, read the receive FIFO buffer until it is empty.
8. Disable the SPI master by writing 0 to `SSIENR`.

20.5.3. Slave SPI and SSP Serial Transfers

Figure 155. Slave SPI or SSP Serial Transfer Software Flow

To complete a continuous serial transfer from a serial master to the SPI slave, follow these steps:

1. If the SPI slave is enabled, disable it by writing 0 to SSIENR.
2. Set up the SPI control registers for the transfer. You can set these registers in any order.

- Write `CTRLR0` (for SPI transfers, set `SCPH` and `SCPOL` identical to the master device).
 - Write `TXFTLR` and `RXFTLR` to set FIFO buffer threshold levels.
 - Write the `IMR` register to set up interrupt masks.
3. Enable the SPI slave by writing 1 to the `SSIENR` register.
 4. If the transfer mode is transmit and receive (`TMOD= 0`) or transmit only (`TMOD= 1`), write data for transmission to the master into the transmit FIFO buffer (write `DR`). If the transfer mode is receive only (`TMOD= 2`), you need not write data into the transmit FIFO buffer. The current value in the transmit shift register is retransmitted.
 5. The SPI slave is now ready for the serial transfer. The transfer begins when a serial-master device selects the SPI slave.
 6. When the transfer is underway, the `BUSY` status can be polled to return the transfer status. If a transmit FIFO empty interrupt request is made, write the transmit FIFO buffer (write `DR`). If a receive FIFO full interrupt request is made, read the receive FIFO buffer (read `DR`).
 7. The transfer ends when the serial master removes the select input to the SPI slave. When the transfer is completed, the `BUSY` status is reset to 0.
 8. If the transfer mode is not transmit only (`TMOD != 1`), read the receive FIFO buffer until empty.
 9. Disable the SPI slave by writing 0 to `SSIENR`.

20.5.4. Slave Microwire Serial Transfers

For the SPI slave, the Microwire protocol operates in much the same way as the SPI protocol. The SPI slave does not decode the control frame.

20.5.5. Software Control for Slave Selection

When using software to select slave devices, the input select lines from serial slave devices is connected to a single slave select output on the SPI master.

20.5.5.1. Example: Slave Selection Software Flow for SPI Master

1. If the SPI master is enabled, disable it by writing 0 to `SSIENR`.
2. Write `CTRLR0` to match the required transfer.
3. If the transfer is receive only, write the number of frames into `CTRLR1`.
4. Write `BAUDR` to set the transfer baud rate.
5. Write `TXFTLR` and `RXFTLR` to set FIFO buffer threshold levels.
6. Write `IMR` register to set interrupt masks.
7. Write `SER` register bit 0 to 1 to select slave 1 in this example.
8. Write `SSIENR` register bit 0 to 1 to enable SPI master.

20.5.5.2. Example: Slave Selection Software Flow for SPI Slave

1. If the SPI slave is enabled, disable it by writing 0 to SSIENR.
2. Write CTRLR0 to match the required transfer.
3. Write TXFTLR and RXFTLR to set FIFO buffer threshold levels.
4. Write IMR register to set interrupt masks.
5. Write SSIENR register bit 0 to 1 to enable SPI slave.
6. If the SPI slave transmits data, write data into TX FIFO buffer.

Note: All other SPI slaves are disabled (SSIENR = 0) and therefore will not respond to an active level on their `ss_in_n` port.

The FIFO buffer depth (FIFO_DEPTH) for both the RX and TX buffers in the SPI controller is 256 entries.

20.5.6. DMA Controller Operation

To enable the DMA controller interface on the SPI controller, you must write the DMA Control Register (DMACR). Writing a 1 to the TDMAE bit field of DMACR register enables the SPI controller transmit handshaking interface. Writing a 1 to the RDMAE bit field of the DMACR register enables the SPI controller receive handshaking.†

Related Information

[DMA Controller](#) on page 1969

For details about the DMA controller, refer to the *DMA Controller* chapter.

20.5.6.1. Transmit FIFO Buffer Underflow

During SPI serial transfers, transmit FIFO buffer requests are made to the DMA Controller whenever the number of entries in the transmit FIFO buffer is less or equal to the value in DMA Transmit Data Level Register (DMATDLR); also known as the watermark level. The DMA Controller responds by writing a burst of data to the transmit FIFO buffer, of length specified as DMA burst length.†

Note: Data should be fetched from the DMA often enough for the transmit FIFO buffer to perform serial transfers continuously, that is, when the FIFO buffer begins to empty, another DMA request should be triggered. Otherwise, the FIFO buffer will run out of data (underflow). To prevent this condition, you must set the watermark level correctly.†

Related Information

[DMA Controller](#) on page 1969

For details about the DMA burst length microcode setup, refer to the *DMA Controller* chapter.

20.5.6.2. Transmit FIFO Watermark

Therefore, the goal in choosing a watermark level is to minimize the number of transactions per block, while at the same time keeping the probability of an underflow condition to an acceptable level. In practice, this is a function of the ratio of the rate at which the SPI transmits data to the rate at which the DMA can respond to destination burst requests. †

20.5.6.2.1. Example 1: Transmit FIFO Watermark Level = 64

Consider the example where the assumption is made: †

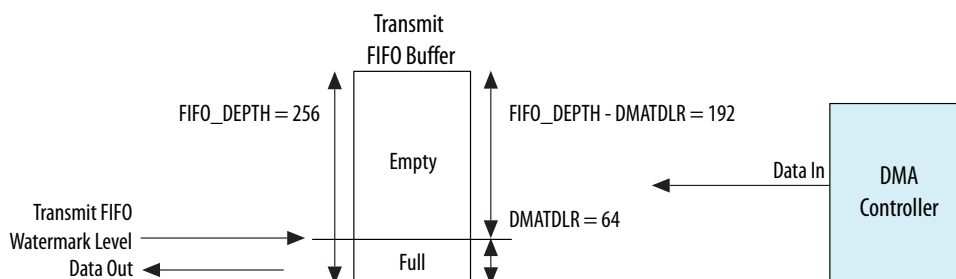

$$\text{DMA burst length} = \text{FIFO_DEPTH} - \text{DMATDLR}$$

Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO buffer.

Consider the following:

- Transmit FIFO watermark level = $\text{DMATDLR} = 64$ †
- DMA burst length = $\text{FIFO_DEPTH} - \text{DMATDLR} = 192$ †
- SPI transmit $\text{FIFO_DEPTH} = 256$ †
- Block transaction size = 960 †

Figure 156. Transmit FIFO Watermark Level = 64

The number of burst transactions needed equals the block size divided by the number of data items per burst:

$$\text{Block transaction size/DMA burst length} = 960/192 = 5$$

The number of burst transactions in the DMA block transfer is 5. But the watermark level, DMATDLR , is quite low. Therefore, there is a high probability that the SPI serial transmit line will need to transmit data when there is no data left in the transmit FIFO buffer. This is a transmit underflow condition. This occurs because the DMA has not had time to service the DMA request before the FIFO buffer becomes empty.

20.5.6.2.2. Example 2: Transmit FIFO Watermark Level = 192

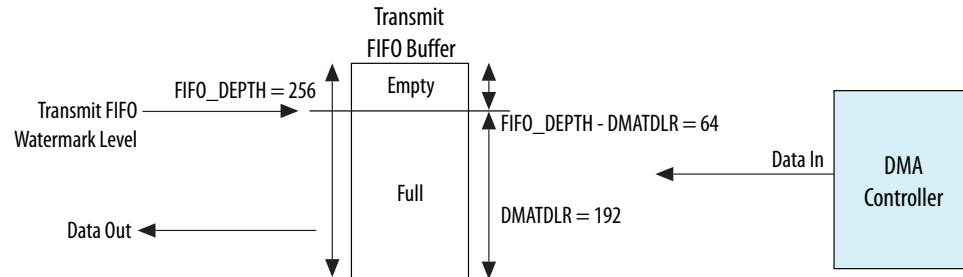

Consider the example where the assumption is made: †

$$\text{DMA burst length} = \text{FIFO_DEPTH} - \text{DMATDLR}$$

Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO buffer. Consider the following:

- Transmit FIFO watermark level = $DMATDLR = 192$ †
- DMA burst length = $FIFO_DEPTH - DMATDLR = 64$ †
- SPI transmit $FIFO_DEPTH = 256$ †
- Block transaction size = 960 †

Figure 157. Transmit FIFO Watermark Level = 192

Number of burst transactions in block: †

Block transaction size/DMA burst length = $960/64 = 15$ †

In this block transfer, there are 15 destination burst transactions in a DMA block transfer. But the watermark level, $DMATDLR$, is high. Therefore, the probability of SPI transmit underflow is low because the DMA controller has plenty of time to service the destination burst transaction request before the SPI transmit FIFO buffer becomes empty. †

This case has a lower probability of underflow at the expense of more burst transactions per block. This provides a potentially greater amount of bursts per block and worse bus utilization than the former case.

20.5.6.3. Transmit FIFO Buffer Overflow

Setting the DMA transaction burst length to a value greater than the watermark level that triggers the DMA request may cause overflow when there is not enough space in the transmit FIFO buffer to service the destination burst request. Therefore, the following equation must be adhered to in order to avoid overflow: †

$$DMA \text{ burst length} \leq FIFO_DEPTH - DMATDLR$$

In Example 2: Transmit Watermark Level = 192, the amount of space in the transmit FIFO buffer at the time of the burst request is made is equal to the DMA burst length. Thus, the transmit FIFO buffer may be full, but not overflowed, at the completion of the burst transaction.

Therefore, for optimal operation, DMA burst length should be set at the FIFO buffer level that triggers a transmit DMA request; that is: †

$$DMA \text{ burst length} = FIFO_DEPTH - DMATDLR$$

Adhering to this equation reduces the number of DMA bursts needed for block transfer, and this in turn improves bus utilization. †

The transmit FIFO buffer will not be full at the end of a DMA burst transfer if the SPI controller has successfully transmitted one data item or more on the serial transmit line during the transfer. †

Related Information

[Transmit FIFO Watermark](#) on page 4012

20.5.6.4. Receive FIFO Buffer Overflow

During SPI serial transfers, receive FIFO buffer requests are made to the DMA whenever the number of entries in the receive FIFO buffer is at or above the DMA Receive Data Level Register, that is $DMARDLR + 1$. This is known as the watermark level. The DMA responds by fetching a burst of data from the receive FIFO buffer. †

Data should be fetched by the DMA often enough for the receive FIFO buffer to accept serial transfers continuously, that is, when the FIFO buffer begins to fill, another DMA transfer is requested. Otherwise the FIFO buffer will fill with data (overflow). To prevent this condition, the user must set the watermark level correctly. †

20.5.6.5. Choosing Receive Watermark Level

Similar to choosing the transmit watermark level, the receive watermark level, $DMATDLR + 1$, should be set to minimize the probability of overflow. It is a trade off between the number of DMA burst transactions required per block versus the probability of an overflow occurring. †

Related Information

[Texas Instruments Synchronous Serial Protocol \(SSP\)](#) on page 4000

20.5.6.6. Receive FIFO Buffer Underflow

Setting the source transaction burst length greater than the watermark level can cause underflow where there is not enough data to service the source burst request. Therefore, the following equation must be adhered to avoid underflow: †

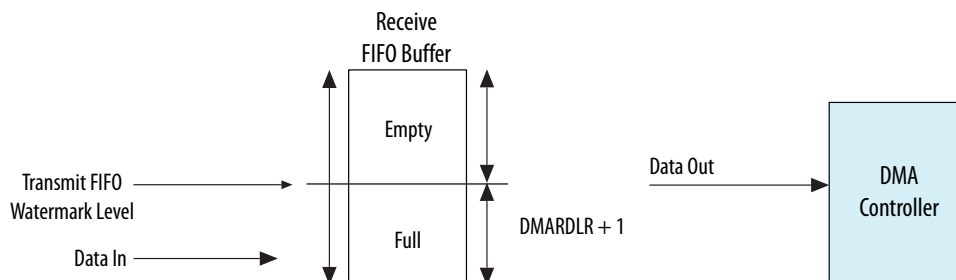

$$\text{DMA burst length} = \text{DMATDLR} + 1$$

If the number of data items in the receive FIFO buffer is equal to the source burst length at the time of the burst request is made, the receive FIFO buffer may be emptied, but not underflowed, at the completion of the burst transaction. For optimal operation, DMA burst length should be set at the watermark level, $DMATDLR + 1$. †

Adhering to this equation reduces the number of DMA bursts in a block transfer, which in turn can improve bus utilization. †

Note: The receive FIFO buffer will not be empty at the end of the source burst transaction if the SPI controller has successfully received one data item or more on the serial receive line during the burst. †

20.6.1.3. ctrlr1

Control Register 1
This register exists only when the DW_apb_ssi is configured as a master device. When the DW_apb_ssi is configured as a serial slave, writing to this location has no effect; reading from this location returns 0. Control register 1 controls the end of serial transfers when in receive-only mode. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register.

Module Instance	Base Address	Register Address
i_spim_0_spim	0xFFDA4000	0xFFDA4004
i_spim_1_spim	0xFFDA5000	0xFFDA5004

Offset: 0x4

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ndf RW 0x0															

ctrlr1 Fields

Bit	Name	Description	Access	Reset
15:0	ndf	Number of Data Frames. When TMOD = 10 or TMOD = 11, this register field sets the number of data frames to be continuously received by the DW_apb_ssi. The DW_apb_ssi continues to receive serial data until the number of data frames received is equal to this register value plus 1, which enables you to receive up to 64 KB of data in a continuous transfer. When the DW_apb_ssi is configured as a serial slave, the transfer continues for as long as the slave is selected. Therefore, this register serves no purpose and is not present when the DW_apb_ssi is configured as a serial slave.	RW	0x0

20.6.1.4. spienr

SSI Enable Register

Module Instance	Base Address	Register Address

2	mhs	<p>Microwire Handshaking. Relevant only when the DW_apb_ssi is configured as a serial-master device. When configured as a serial slave, this bit field has no functionality. Used to enable and disable the busy/ready handshaking interface for the Microwire protocol. When enabled, the DW_apb_ssi checks for a ready status from the target slave, after the transfer of the last data/control bit, before clearing the BUSY status in the SR register. 0: handshaking interface is disabled 1: handshaking interface is enabled</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>DISABLED</td></tr><tr><td>0x1</td><td>ENABLED</td></tr></table>	Value	Description	0x0	DISABLED	0x1	ENABLED	RW	0x0
Value	Description									
0x0	DISABLED									
0x1	ENABLED									
1	mdd	<p>Microwire Control. Defines the direction of the data word when the Microwire serial protocol is used. When this bit is set to 0, the data word is received by the DW_apb_ssi MacroCell from the external serial device. When this bit is set to 1, the data word is transmitted from the DW_apb_ssi MacroCell to the external serial device.</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>RXMODE</td></tr><tr><td>0x1</td><td>TXMODE</td></tr></table>	Value	Description	0x0	RXMODE	0x1	TXMODE	RW	0x0
Value	Description									
0x0	RXMODE									
0x1	TXMODE									
0	mwmod	<p>Microwire Transfer Mode. Defines whether the Microwire transfer is sequential or non-sequential. When sequential mode is used, only one control word is needed to transmit or receive a block of data words. When non-sequential mode is used, there must be a control word for each data word that is transmitted or received. 0: non-sequential transfer 1: sequential transfer</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>NONSEQ</td></tr><tr><td>0x1</td><td>SEQ</td></tr></table>	Value	Description	0x0	NONSEQ	0x1	SEQ	RW	0x0
Value	Description									
0x0	NONSEQ									
0x1	SEQ									

20.6.1.6. ser

Slave Enable Register.
This register is valid only when the DW_apb_ssi is configured as a master

device. When the DW_apb_ssi is configured as a serial slave, writing to this location has no effect; reading from this location returns 0. The register enables the individual slave select output lines from the DW_apb_ssi master. Up to 16 slave-select output pins are available on the DW_apb_ssi master. You cannot write to this register when DW_apb_ssi is busy and when SSI_EN = 1.

Module Instance	Base Address	Register Address
i_spim_0_spim	0xFFDA4000	0xFFDA4010
i_spim_1_spim	0xFFDA5000	0xFFDA5010

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved												ser RW 0x0			

ser Fields

Bit	Name	Description	Access	Reset						
3:0	ser	<p>Slave Select Enable Flag. Each bit in this register corresponds to a slave select line (ss_x_n) from the DW_apb_ssi master. When a bit in this register is set (1), the corresponding slave select line from the master is activated when a serial transfer begins. It should be noted that setting or clearing bits in this register have no effect on the corresponding slave select outputs until a transfer is started. Before beginning a transfer, you should enable the bit in this register that corresponds to the slave device with which the master wants to communicate. When not operating in broadcast mode, only one bit in this field should be set. 1: Selected 0: Not Selected</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0x0</td><td>NOTSELECTED</td></tr><tr><td>0x1</td><td>SELECTED</td></tr></tbody></table>	Value	Description	0x0	NOTSELECTED	0x1	SELECTED	RW	0x0
Value	Description									
0x0	NOTSELECTED									
0x1	SELECTED									

20.6.1.7. baudr

Baud Rate Select.
This register is valid only when the DW_apb_ssi is configured as a master device. When the DW_apb_ssi is configured as a serial slave, writing to this location has no effect; reading from this location returns 0. The register derives the frequency of the serial clock that regulates the data transfer. The 16-bit field in this register defines the ssi_clk divider value. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register.

Module Instance	Base Address	Register Address
i_spim_0_spim	0xFFDA4000	0xFFDA4014
i_spim_1_spim	0xFFDA5000	0xFFDA5014

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sckdv RW 0x0															

baudr Fields

Bit	Name	Description	Access	Reset
15:0	sckdv	<p>SSI Clock Divider. The LSB for this field is always set to 0 and is unaffected by a write operation, which ensures an even value is held in this register. If the value is 0, the serial output clock (sclk_out) is disabled. The frequency of the sclk_out is derived from the following equation:</p> $F_{sclk_out} = F_{ssi_clk} / SCKDV$ <p>where SCKDV is any even value between 2 and 65534. For example: for Fssi_clk = 3.6864MHz and SCKDV = 2 Fclk_out = 3.6864/2 = 1.8432MHz</p>	RW	0x0

20.6.1.8. txftlr

Transmit FIFO Threshold Level.
This register controls the threshold value for the transmit FIFO memory.
The DW_apb_ssi is enabled and disabled by writing to the SSIENR register.

Module Instance	Base Address	Register Address
i_spim_0_spim	0xFFDA4000	0xFFDA4018
i_spim_1_spim	0xFFDA5000	0xFFDA5018

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								tft RW 0x0							

txftlr Fields

Bit	Name	Description	Access	Reset
7:0	tft	Transmit FIFO Threshold. Controls the level of entries (or below) at which the transmit FIFO controller triggers an interrupt. The FIFO depth is configurable in the range 2-256; this register is sized to the number of address bits needed to access the FIFO. If you attempt to set this value greater than or equal to the depth of the FIFO, this field is not written and retains its current value. When the number of transmit FIFO entries is less than or equal to this value, the transmit FIFO empty interrupt is triggered.	RW	0x0

20.6.1.9. rxftlr

Receive FIFO Threshold level.
This register controls the threshold value for the receive FIFO memory.
The DW_apb_ssi is enabled and disabled by writing to the SSIENR register.

Module Instance	Base Address	Register Address
i_spim_0_spim	0xFFDA4000	0xFFDA401C
i_spim_1_spim	0xFFDA5000	0xFFDA501C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								rft RW 0x0							

rxftlr Fields

Bit	Name	Description	Access	Reset
7:0	rft	Receive FIFO Threshold. Controls the level of entries (or above) at which the receive FIFO controller triggers an interrupt. The FIFO depth is configurable in the range 2-256. This register is sized to the number of address bits needed to access the FIFO. If you attempt to set this value greater than the depth of the FIFO, this field is not written and retains its current value. When the number of receive FIFO entries is greater than or equal to this value + 1, the receive FIFO full interrupt is triggered.	RW	0x0

20.6.1.25. dr

The data register is a 16-bit read/write buffer for the transmit/receive FIFOs. When the register is read, data in the receive FIFO buffer is accessed. When it is written to, data are moved into the transmit FIFO buffer; a write can occur only when SSI_EN = 1. FIFOs are reset when SSI_EN = 0. Note that the data register occupies thirty-six 32-bit address locations of the memory map to facilitate burst transfers. Writing to any of these address locations has the same effect as pushing the data from the bus into the TxFIFO and reading from any of these location has the same effect as popping data from the Rx FIFO onto the bus.

Module Instance	Base Address	Register Address
i_spim_0_spim	0xFFDA4000	0xFFDA4060 to 0xFFDA40EC
i_spim_1_spim	0xFFDA5000	0xFFDA5060 to 0xFFDA50EC

Offset: 0x60 to 0xEC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

dr RW 0x0															

dr Fields

Bit	Name	Description	Access	Reset
15:0	dr	Data Register. When writing to this register, you must right-justify the data. Read data are automatically right-justified. Read = Receive FIFO buffer Write = Transmit FIFO buffer	RW	0x0

20.6.1.26. rx_sample_dly

RX Sample Delay.
This register controls the number of ssi_clk cycles that are delayed (from the default sample time) before the actual sample of the rxd input occurs. It is impossible to write to this register when the SPI master is enabled. The SPI master is enabled and disabled by writing to the SSIENR register.

Module Instance	Base Address	Register Address
i_spim_0_spim	0xFFDA4000	0xFFDA40F0
i_spim_1_spim	0xFFDA5000	0xFFDA50F0

Offset: 0xF0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								rsd RW 0x0							

rx_sample_dly Fields

Bit	Name	Description	Access	Reset
7:0	rsd	Rxd Sample Delay. This register is used to delay the sample of the rxd input port. Each value represents a single ssi_clk delay on the sample of rxd. NOTE: You must program the rsd field to 0x1 or greater for correct operation. In addition, if you program this register to a value that exceeds the depth of the internal shift registers (SSI_RX_DLY_SR_DEPTH), zero delay is applied to the rxd sample and the interface does not function correctly.	RW	0x0

20.6.1.27. msticr

20.6.2.2. ctrlr0

Control Register 0:
This register controls the serial data transfer. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register.

Module Instance	Base Address	Register Address
i_spis_0_spis	0xFFDA2000	0xFFDA2000
i_spis_1_spis	0xFFDA3000	0xFFDA3000

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Value	Description									
0x1	TESTMODE									
10	slv_oe	<p>Slave Output Enable. Relevant only when the DW_apb_ssi is configured as a serial-slave device. When configured as a serial master, this bit field has no functionality. This bit enables or disables the setting of the ssi_oe_n output from the DW_apb_ssi serial slave. When SLV_OE = 1, the ssi_oe_n output can never be active. When the ssi_oe_n output controls the tri-state buffer on the txd output from the slave, a high impedance state is always present on the slave txd output when SLV_OE = 1. This is useful when the master transmits in broadcast mode (master transmits data to all slave devices). Only one slave may respond with data on the master rxd line. This bit is enabled after reset and must be disabled by software (when broadcast mode is used), if you do not want this device to respond with data. 0 - Slave txd is enabled 1 - Slave txd is disabled</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>ENABLED</td></tr><tr><td>0x1</td><td>DISABLED</td></tr></table>	Value	Description	0x0	ENABLED	0x1	DISABLED	RW	0x0

9:8	tmod	<p>Transfer Mode. Selects the mode of transfer for serial communication. This field does not affect the transfer duplicity. Only indicates whether the receive or transmit data are valid. In transmit-only mode, data received from the external device is not valid and is not stored in the receive FIFO memory; it is overwritten on the next transfer. In receive-only mode, transmitted data are not valid. After the first write to the transmit FIFO, the same word is retransmitted for the duration of the transfer. In transmit-and-receive mode, both transmit and receive data are valid. The transfer continues until the transmit FIFO is empty. Data received from the external device are stored into the receive FIFO memory, where it can be accessed by the host processor. 00 - Transmit & Receive 01 - Transmit Only 10 - Receive Only 11 - Reserved</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>TXRX</td></tr><tr><td>0x1</td><td>TXONLY</td></tr></table>	Value	Description	0x0	TXRX	0x1	TXONLY	RW	0x0

20.6.2.5. txftlr

Transmit FIFO Threshold Level.
This register controls the threshold value for the transmit FIFO memory. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register.

Module Instance	Base Address	Register Address
i_spis_0_spis	0xFFDA2000	0xFFDA2018
i_spis_1_spis	0xFFDA3000	0xFFDA3018

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								tft RW 0x0							

txftlr Fields

Bit	Name	Description	Access	Reset
7:0	tft	Transmit FIFO Threshold. Controls the level of entries (or below) at which the transmit FIFO controller triggers an interrupt. The FIFO depth is configurable in the range 2-256; this register is sized to the number of address bits needed to access the FIFO. If you attempt to set this value greater than or equal to the depth of the FIFO, this field is not written and retains its current value. When the number of transmit FIFO entries is less than or equal to this value, the transmit FIFO empty interrupt is triggered.	RW	0x0

20.6.2.6. rxftlr

Receive FIFO Threshold level.
This register controls the threshold value for the receive FIFO memory.
The DW_apb_ssi is enabled and disabled by writing to the SSIENR register.

Module Instance	Base Address	Register Address
i_spis_0_spis	0xFFDA2000	0xFFDA201C
i_spis_1_spis	0xFFDA3000	0xFFDA301C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								rft RW 0x0							

rxftlr Fields

Bit	Name	Description	Access	Reset
7:0	rft	Receive FIFO Threshold. Controls the level of entries (or above) at which the receive FIFO controller triggers an interrupt. The FIFO depth is configurable in the range 2-256. This register is sized to the number of address bits needed to access the FIFO. If you attempt to set this value greater than the depth of the FIFO, this field is not written and retains its current value. When the number of receive FIFO entries is greater than or equal to this value + 1, the receive FIFO full interrupt is triggered.	RW	0x0

The data register is a 16-bit read/write buffer for the transmit/receive FIFOs. When the register is read, data in the receive FIFO buffer is accessed. When it is written to, data are moved into the

transmit FIFO buffer; a write can occur only when SSI_EN = 1. FIFOs are reset when SSI_EN = 0. Note that the data register occupies thirty-six 32-bit address locations of the memory map to facilitate burst transfers. Writing to any of these address locations has the same effect as pushing the data from the bus into the TxFIFO and reading from any of these location has the same effect as popping data from the RxFIFO onto the bus.

21. I²C Controller

The I²C controller provides support for a communication link between integrated circuits on a board. It is a simple two-wire bus which consists of a serial data line (SDA) and a serial clock (SCL) for use in applications such as temperature sensors and voltage level translators to EEPROMs, A/D and D/A converters, CODECs, and many types of microprocessors. †

The hard processor system (HPS) provides five I²C controllers to enable system software to communicate serially with I²C buses. Each I²C controller can operate in master or slave mode, and support standard mode of up to 100 Kbps or fast mode of up to 400 Kbps. These I²C controllers are instances of the Synopsys DesignWare APB I²C (DW_apb_i2c) controller.

Each I²C controller must be programmed to operate in either master or slave mode only. Operating as a master and slave simultaneously is not supported. † ⁽⁵⁵⁾

21.1. Features of the I²C Controller

The I²C controller has the following features:

- Maximum clock speed of up to 400 Kbps
- Standard clock speed 100 kbps
- One of the following I²C operations:
 - A master in an I²C system and programmed only as a master †
 - A slave in an I²C system and programmed only as a slave †
- 7- or 10-bit addressing †
- Mixed read and write combined-format transactions in both 7-bit and 10-bit addressing mode †

†Paragraphs marked with the dagger (†) symbol are Synopsys Proprietary. Used with permission.

- Bulk transmit mode †
- Transmit and receive buffers †
- Handles bit and byte waiting at all bus speeds †
- DMA handshaking interface †

Three of the five I²Cs, provide support for EMAC communication. They provide flexibility for the EMACs to use MDIO or I²C for PHY communication and can also be used as general purpose.

- I2C_EMAC0
- I2C_EMAC1
- I2C_EMAC2

The remaining two I²Cs are intended for general purpose.

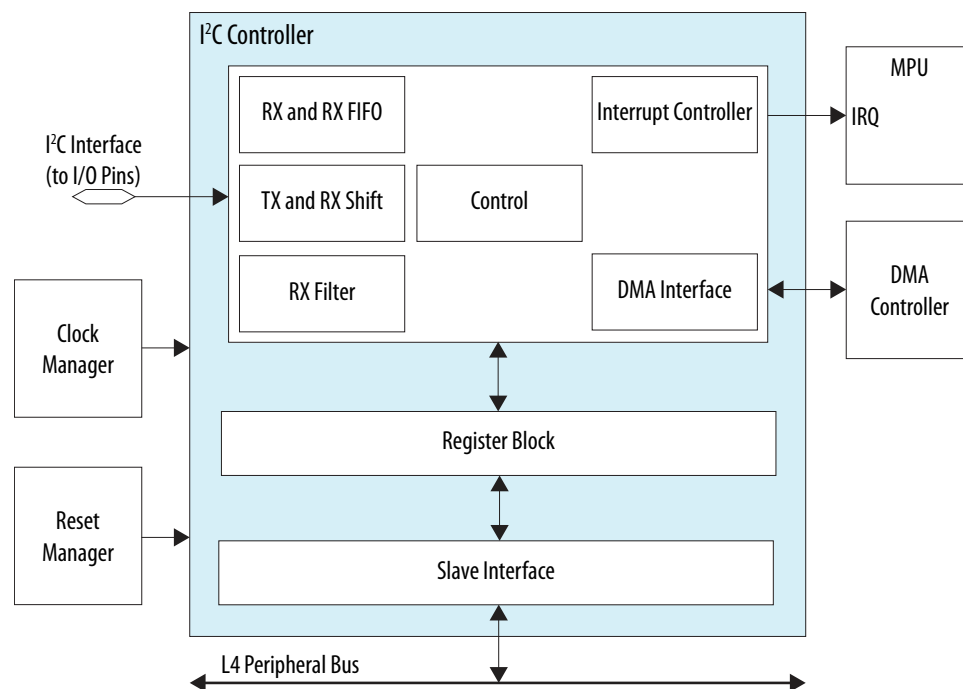

- I2C0
- I2C1

21.2. I²C Controller Block Diagram and System Integration

The I²C controller consists of an internal slave interface, an I²C interface, and FIFO logic to buffer data between the two interfaces. †

The host processor accesses data, control, and status information about the I²C controller through a 32-bit slave interface.

Figure 159. I²C Controller Block Diagram

The I²C controller consists of the following modules and interfaces:

- Slave interface for control and status register (CSR) accesses and DMA transfers, allowing a master to access the CSRs and the DMA to read or write data directly.
- Two FIFO buffers for transmit and receive data, which hold the Rx FIFO and Tx FIFO buffer register banks and controllers, along with their status levels. †
- Shift logic for parallel-to-serial and serial-to-parallel conversion
 - Rx shift – Receives data into the design and extracts it in byte format. †
 - Tx shift – Presents data supplied by CPU for transfer on the I²C bus. †
- Control logic responsible for implementing the I²C protocol.
- DMA interface that generates handshaking signals to the DMA controller in order to automate the data transfer without CPU intervention. †
- Interrupt controller that generates raw interrupts and interrupt flags, allowing them to be set and cleared. †
- Receive filter for detecting events, such as start and stop conditions, in the bus; for example, start, stop and arbitration lost. †

21.3. I²C Controller Signal Description

All instances of the I²C controller connect to external pins through pin multiplexers. Pin multiplexing allows all instances to function simultaneously and independently. The pins must be connected to a pull-up resistors and the I²C bus capacitance cannot exceed 400 pF.

There are five instances of the I²C which can be routed to the HPS I/O pins. Three of these I²C modules can be used for PHY management by the three Ethernet Media Access Controllers within the HPS. For more information about routing the I²C signals to the FPGA and HPS I/O pins, refer to the *HPS Component Interfaces* chapter.

Table 245. I²C Controller Interface HPS I/O Pins

Pin Name	Signal Width	Direction	Description
SCL	1 bit	Bidirectional	Serial clock
SDA	1 bit	Bidirectional	Serial data

Table 246. HPS I²C Signals for FPGA Routing

Signal Name	Signal Width	Direction	Description
i2c<#>_scl	1 bit	Input	Incoming I ² C clock source. This is the input SCL signal
i2c<#>_out_clk	1 bit	Output	Outgoing I ² C clock enable. Output SCL signal. This signal is logically inverted and is synchronous to the HPS peripheral clock
i2c<#>_sda	1 bit	Input	Incoming I ² C data. This is the input SDA signal.
i2c<#>_out_data	1 bit	Output	Outgoing I ² C data enable. Output SDA signal. This signal is logically inverted and is synchronous to the HPS peripheral clock.

Figure 160. I²C Interface in FPGA Fabric

The figure above shows the typical connection on the I²C interface in FPGA fabric with alt_iobuff.

For both I²C clock and data, external IO pins are open drain connection. When output enables i2c_out_data and i2c_out_clk are asserted, external signal will be driven to ground.

21.4. Functional Description of the I²C Controller

21.4.1. Feature Usage

The I²C controller can operate in standard mode (with data rates of up to 100 Kbps) or fast mode (with data rates less than or equal to 400 Kbps). Additionally, fast mode devices are downward compatible. For instance, fast mode devices can communicate with standard mode devices in 0 to 100 Kbps I²C bus system. However, standard mode devices are not upward compatible and should not be incorporated in a fast-mode I²C bus system as they cannot follow the higher transfer rate and therefore unpredictable states would occur. †

You can attach any I²C controller to an I²C-bus and every device can talk with any master, passing information back and forth. There needs to be at least one master (such as a microcontroller or DSP) on the bus and there can be multiple masters, which require them to arbitrate for ownership. Multiple masters and arbitration are explained later in this chapter. †

21.4.2. Behavior

You can control the I²C controller via software to be in either mode:

- An I²C master only, communicating with other I²C slaves.
- An I²C slave only, communicating with one or more I²C masters.

The master is responsible for generating the clock and controlling the transfer of data. The slave is responsible for either transmitting or receiving data to/from the master. The acknowledgement of data is sent by the device that is receiving data, which can be either a master or a slave. As mentioned previously, the I²C protocol also allows multiple masters to reside on the I²C bus and uses an arbitration procedure to determine bus ownership. †

Each slave has a unique address that is determined by the system designer. When a master wants to communicate with a slave, the master transmits a START/RESTART condition that is then followed by the slave's address and a control bit (R/W) to determine if the master wants to transmit data or receive data from the slave. The slave then sends an acknowledge (ACK) pulse after the address. †

If the master (master-transmitter) is writing to the slave (slave-receiver), the receiver receives one byte of data. This transaction continues until the master terminates the transmission with a STOP condition. If the master is reading from a slave (master-receiver), the slave transmits (slave-transmitter) a byte of data to the master, and the master then acknowledges the transaction with an ACK pulse. This transaction continues until the master terminates the transmission by not acknowledging (NACK) the transaction after the last byte is received, and then the master issues a STOP condition or addresses another slave after issuing a RESTART condition. †

Figure 161. Data Transfer on the I²C Bus †

The I²C controller is a synchronous serial interface. The SDA line is a bidirectional signal and changes only while the SCL line is low, except for STOP, START, and RESTART conditions. The output drivers are open-drain or open-collector to perform wire-AND functions on the bus. The maximum number of devices on the bus is limited by only the maximum capacitance specification of 400 pF. Data is transmitted in byte packages. †

21.4.2.1. START and STOP Generation

When operating as a master, putting data into the transmit FIFO causes the I²C controller to generate a START condition on the I²C bus. In order for the master to complete the transfer and issue a STOP condition it must find a transmit FIFO entry tagged with a stop bit. Allowing the transmit FIFO to empty without a stop bit set, the master will stall the transfer by holding the SCL line low. †

When operating as a slave, the I²C controller does not generate START and STOP conditions, as per the protocol. However, if a read request is made to the I²C controller, it holds the SCL line low until read data has been supplied to it. This stalls the I²C bus until read data is provided to the slave I²C controller, or the I²C controller slave is disabled by writing a 0 to bit 0 of IC_ENABLE register. †

21.4.2.2. Combined Formats

The I²C controller supports mixed read and write combined format transactions in both 7-bit and 10-bit addressing modes. †

The I²C controller does not support mixed address and mixed address format—that is, a 7-bit address transaction followed by a 10-bit address transaction or vice versa—combined format transactions. †

To initiate combined format transfers, the IC_RESTART_EN bit in the IC_CON register should be set to 1. With this value set and operating as a master, when the I²C controller completes an I²C transfer, it checks the transmit FIFO and executes the next transfer. If the direction of this transfer differs from the previous transfer, the combined format is used to issue the transfer. If the IC_RESTART_EN is 0, a STOP will be issued followed by a START condition. Another way to generate the RESTART condition is to set the Restart bit [10] of the DATA_CMD register. Regardless if the direction of the transfer changes or not the RESTART condition will be generated. †

21.4.3. Protocol Details

21.4.3.1. START and STOP Conditions

When the bus is idle, both the SCL and SDA signals are pulled high through pull-up resistors on the bus. When the master wants to start a transmission on the bus, the master issues a START condition. This is defined to be a high-to-low transition of the SDA signal while SCL is 1. When the master wants to terminate the transmission, the master issues a STOP condition. This is defined to be a low-to-high transition of the SDA line while SCL is 1. †

The following figure shows the timing of the START and STOP conditions. When data is being transmitted on the bus, the SDA line must be stable when SCL is 1. †

Figure 162. Timing Diagram for START and STOP Conditions

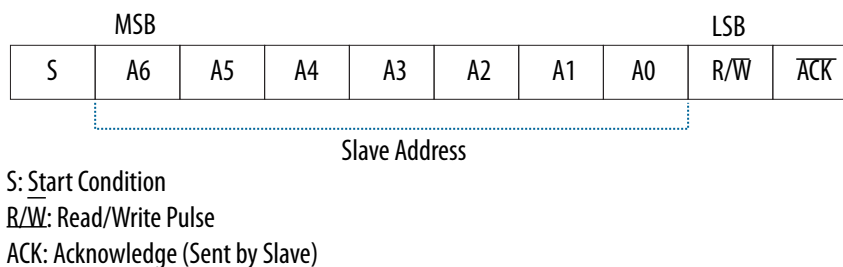

The signal transitions for the START or STOP condition, as shown in the figure, reflect those observed at the output signals of the master driving the I²C bus. Care should be taken when observing the SDA or SCL signals at the input signals of the slave(s), because unequal line delays may result in an incorrect SDA or SCL timing relationship. †

21.4.3.2. Addressing Slave Protocol

21.4.3.2.1. 7-Bit Address Format

During the 7-bit address format, the first seven bits (bits 7:1) of the first byte set the slave address and the LSB bit (bit 0) is the R/W bit as shown in the following figure. When bit 0 (R/W) is set to 0, the master writes to the slave. When bit 0 (R/W) is set to 1, the master reads from the slave. †

Figure 163. 7- Bit Address Format

21.4.3.2.2. 10-Bit Address Format

During 10-bit addressing, two bytes are transferred to set the 10-bit address. The transfer of the first byte contains the following bit definition. The first five bits (bits 7:3) notify the slaves that this is a 10-bit transfer followed by the next two bits (bits 2:1), which set the slaves address bits 9:8, and the LSB bit (bit 0) is the R/W bit. The second byte transferred sets bits 7:0 of the slave address. †

Figure 164. 10-Bit Address Format

The following table defines the special purpose and reserved first byte addresses. †

Table 247. I²C Definition of Bits in First Byte

Slave Address	R/W Bit	Description
0000 000	0	General call address. The I ² C controller places the data in the receive buffer and issues a general call interrupt.
0000 000	1	START byte. For more details, refer to "START BYTE Transfer Protocol"

continued...

Slave Address	R/W Bit	Description
0000 001	X	CBUS address. The I ² C controller ignores these accesses.
0000 010	X	Reserved
0000 011	X	Reserved
0000 1XX	X	Unused
1111 1XX	X	Reserved
1111 0XX	X	10-bit slave addressing.
Note to Table: 'X' indicates do not care.		

Related Information

START BYTE Transfer Protocol on page 4101

21.4.3.3. Transmitting and Receiving Protocol

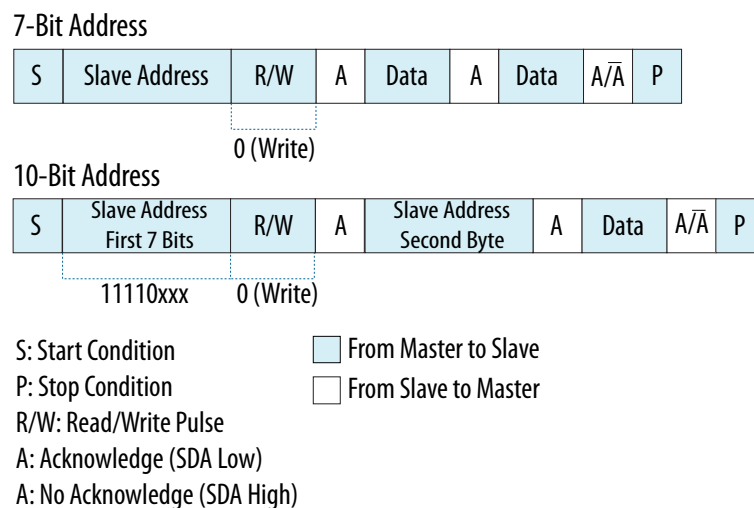

The master can initiate data transmission and reception to or from the bus, acting as either a master-transmitter or master-receiver. A slave responds to requests from the master to either transmit data or receive data to or from the bus, acting as either a slave-transmitter or slave-receiver, respectively. †

21.4.3.3.1. Master-Transmitter and Slave-Receiver

All data is transmitted in byte format, with no limit on the number of bytes transferred per data transfer. After the master sends the address and R/W bit or the master transmits a byte of data to the slave, the slave-receiver must respond with the acknowledge signal (ACK). When a slave-receiver does not respond with an ACK pulse, the master aborts the transfer by issuing a STOP condition. The slave must leave the SDA line high so that the master can abort the transfer. †

If the master-transmitter is transmitting data as shown in the following figure, then the slave-receiver responds to the master-transmitter with an ACK pulse after every byte of data is received. †

Figure 165. Master-Transmitter Protocol †

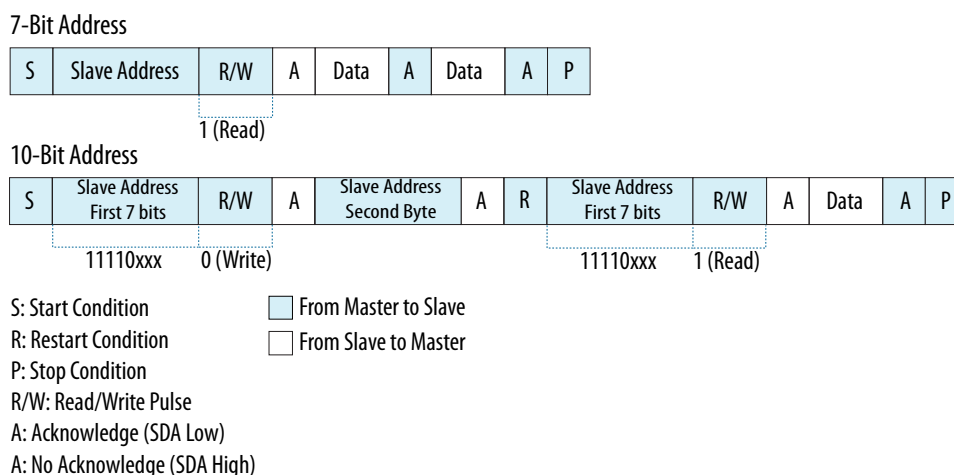

21.4.3.3.2. Master-Receiver and Slave-Transmitter

If the master is receiving data as shown in the following figure, then the master responds to the slave-transmitter with an ACK pulse after a byte of data has been received, except for the last byte. This is the way the master-receiver notifies the slave-transmitter that this is the last byte. The slave-transmitter relinquishes the SDA line after detecting the No Acknowledge (NACK) bit so that the master can issue a STOP condition. †

When a master does not want to relinquish the bus with a STOP condition, the master can issue a RESTART condition. This is identical to a START condition except it occurs after the ACK pulse. Operating in master mode, the I²C controller can then communicate with the same slave using a transfer of a different direction. For a description of the combined format transactions that the I²C controller supports, refer to “Combined Formats” section of this chapter. †

Note: The I²C controller must be inactive on the serial port before the target slave address register, IC_TAR, can be reprogrammed. †

Figure 166. Master-Receiver Protocol †

Related Information

[Combined Formats](#) on page 4098

21.4.3.4. START BYTE Transfer Protocol

The START BYTE transfer protocol is set up for systems that do not have an on-board dedicated I²C hardware module. When the I²C controller is set as a slave, it always samples the I²C bus at the highest speed supported so that it never requires a START BYTE transfer. However, when I²C controller is set as a master, it supports the generation of START BYTE transfers at the beginning of every transfer in case a slave device requires it. This protocol consists of seven zeros being transmitted followed by a 1, as illustrated in the following figure. This allows the processor that is polling the bus to under-sample the address phase until the microcontroller detects a 0. Once the microcontroller detects a 0, it switches from the under sampling rate to the correct rate of the master. †

Figure 167. START BYTE Transfer †

The START BYTE has the following procedure: †

1. Master generates a START condition. †
2. Master transmits the START byte (0000 0001). †
3. Master transmits the ACK clock pulse. (Present only to conform with the byte handling format used on the bus) †
4. No slave sets the ACK signal to 0. †
5. Master generates a RESTART (R) condition. †

A hardware receiver does not respond to the START BYTE because it is a reserved address and resets after the RESTART condition is generated. †

21.4.4. Multiple Master Arbitration

The I²C controller bus protocol allows multiple masters to reside on the same bus. If there are two masters on the same I²C-bus, there is an arbitration procedure if both try to take control of the bus at the same time by simultaneously generating a START condition. Once a master (for example, a microcontroller) has control of the bus, no other master can take control until the first master sends a STOP condition and places the bus in an idle state. †

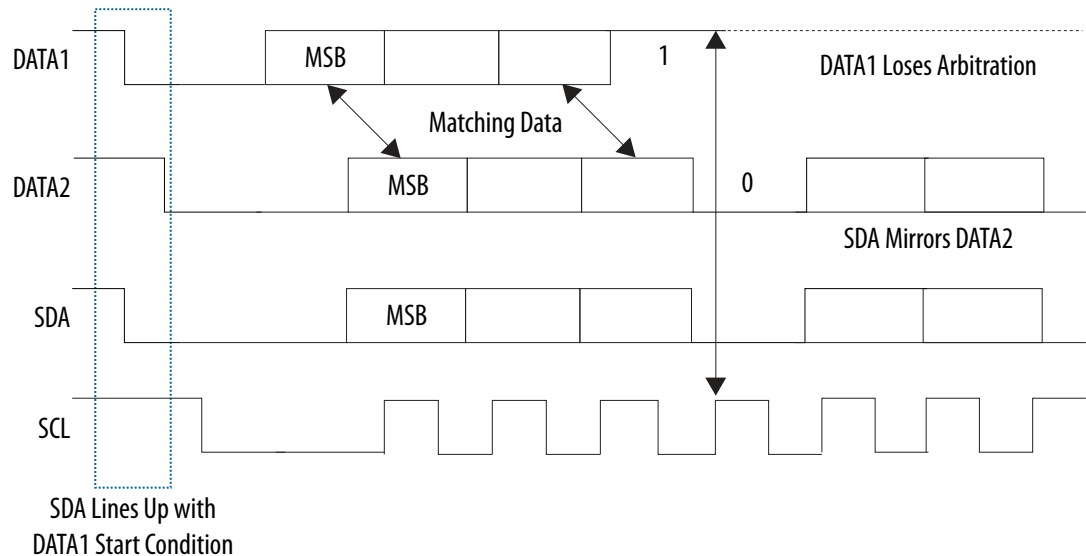

Arbitration takes place on the SDA line, while the SCL line is 1. The master, which transmits a 1 while the other master transmits 0, loses arbitration and turns off its data output stage. The master that lost arbitration can continue to generate clocks until the end of the byte transfer. If both masters are addressing the same slave device, the arbitration could go into the data phase. †

Upon detecting that it has lost arbitration to another master, the I²C controller stops generating SCL. †

The following figure illustrates the timing of two masters arbitrating on the bus.

Figure 168. Multiple Master Arbitration †

The bus control is determined by address or master code and data sent by competing masters, so there is no central master nor any order of priority on the bus. †

Arbitration is not allowed between the following conditions: †

- A RESTART condition and a data bit †
- A STOP condition and a data bit †
- A RESTART condition and a STOP condition †

Slaves are not involved in the arbitration process. †

21.4.4.1. Clock Synchronization

When two or more masters try to transfer information on the bus at the same time, they must arbitrate and synchronize the SCL clock. All masters generate their own clock to transfer messages. Data is valid only during the high period of SCL clock. Clock synchronization is performed using the wired-AND connection to the SCL signal. When the master transitions the SCL clock to 0, the master starts counting the low time of the SCL clock and transitions the SCL clock signal to 1 at the beginning of the next clock period. However, if another master is holding the SCL line to 0, then the master goes into a HIGH wait state until the SCL clock line transitions to 1. †

All masters then count off their high time, and the master with the shortest high time transitions the SCL line to 0. The masters then counts out their low time and the one with the longest low time forces the other master into a HIGH wait state. Therefore, a synchronized SCL clock is generated, which is illustrated in the following figure. Optionally, slaves may hold the SCL line low to slow down the timing on the I²C bus. †

Figure 169. Multiple Master Clock Synchronization †

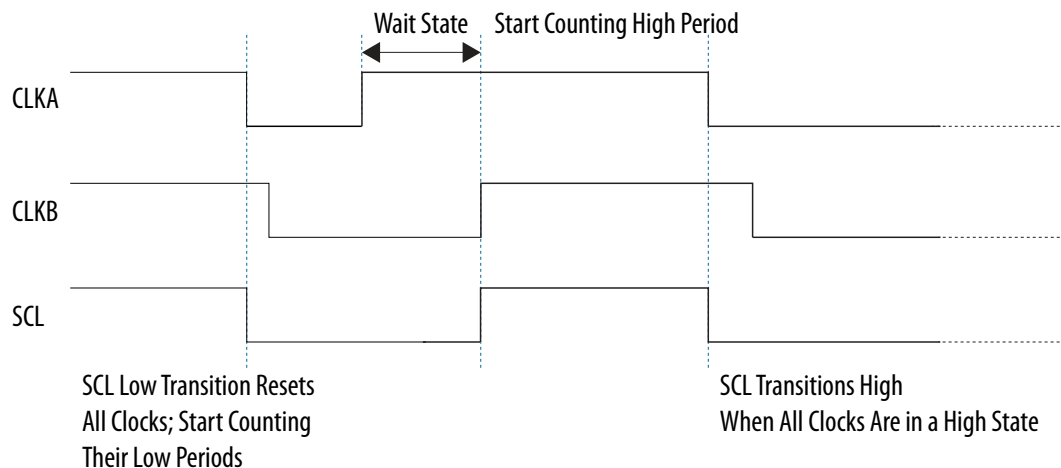

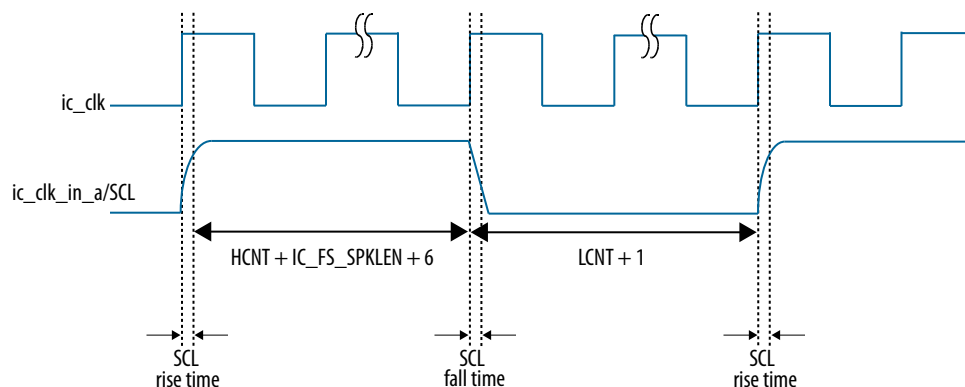

Figure 170. Impact of SCL Rise Time and Fall Time on Generated SCL

The following equations can be used to compute SCL high and low time:

$$\text{SCL_High_time} = [(\text{HCNT} + \text{IC_FS_SPKLEN} + 6) * \text{ic_clk}] + \text{SCL_Fall_time}$$

$$\text{SCL_Low_time} = [(\text{LCNT} + 1) * \text{ic_clk}] - \text{SCL_Fall_time} + \text{SCL_Rise_time}$$

21.4.5. Clock Frequency Configuration

When you configure the I²C controller as a master, the SCL count registers must be set before any I²C bus transaction can take place in order to ensure proper I/O timing.
† There are four SCL count registers:

- Standard speed I²C clock SCL high count, IC_SS_SCL_HCNT †
- Standard speed I²C clock SCL low count, IC_SS_SCL_LCNT †
- Fast speed I²C clock SCL high count, IC_FS_SCL_HCNT †
- Fast speed I²C clock SCL low count, IC_FS_SCL_LCNT †

It is not necessary to program any of the SCL count registers if the I²C controller is enabled to operate only as an I²C slave, since these registers are used only to determine the SCL timing requirements for operation as an I²C master. †

21.4.5.1. Minimum High and Low Counts

When the I²C controller operates as an I²C master in both transmit and receive transfers, the minimum value that can be programmed in the SCL low count registers is 8 while the minimum value allowed for the SCL high count registers is 6. †

The minimum value of 8 for the low count registers is due to the time required for the I²C controller to drive SDA after a negative edge of SCL. The minimum value of 6 for the high count register is due to the time required for the I²C controller to sample SDA during the high period of SCL. †

The I²C controller adds one cycle to the low count register values in order to generate the low period of the SCL clock.

The I²C controller adds seven cycles to the high count register values in order to generate the high period of the SCL clock. This is due to the following factors: †

- The digital filtering applied to the SCL line incurs a delay of four `14_sp_clk` cycles. This filtering includes metastability removal and a 2-out-of-3 majority vote processing on SDA and SCL edges. †
- Whenever SCL is driven 1 to 0 by the I²C controller—that is, completing the SCL high time—an internal logic latency of three `14_sp_clk` cycles incurs. †

Consequently, the minimum SCL low time of which the I²C controller is capable is nine (9) `14_sp_clk` periods (8+1), while the minimum SCL high time is thirteen (13) `14_sp_clk` periods (6+1+3+3). †

Note: The `ic_fs_spklen` register must be set before any I²C bus transaction can take place to ensure stable operation. This register sets the duration measured in `ic_clk` cycles, of the longest spike in the SCL or SDA lines that will be filtered out by the spike suppression logic. †

21.4.5.1.1. Calculating High and Low Counts

The calculations below show an example of how to calculate SCL high and low counts for each speed mode in the I²C controller.

The equation to calculate the proper number of `14_sp_clk` clock pulses required for setting the proper SCL clocks high and low times is as follows: †

Table 248. Equation

```

IC_HCNT = ceil(MIN_SCL_HIGHTime*OSCFREQ)
IC_LCNT = ceil(MIN_SCL_LOWtime*OSCFREQ)
MIN_SCL_HIGHTime = minimum high period
MIN_SCL_HIGHTime =
4000 ns for 100 kbps
600 ns for 400 kbps
60 ns for 3.4 Mbs, bus loading = 100pF
160 ns for 3.4 Mbs, bus loading = 400pF
MIN_SCL_LOWtime = minimum low period
MIN_SCL_LOWtime =
4700 ns for 100 kbps
1300 ns for 400 kbps
120 ns for 3.4Mbs, bus loading = 100pF
320 ns for 3.4Mbs, bus loading = 400pF
OSCFREQ = 14_sp_clk clock frequency (Hz)

```

Example 3. Calculating High and Low Counts

```

OSCFREQ = 100 MHz
I2Cmode = fast, 400 kbps
MIN_SCL_HIGHTime = 600 ns
MIN_SCL_LOWtime = 1300 ns

IC_HCNT = ceil(600 ns * 100 MHz) IC_HCNTSCL PERIOD = 60
IC_LCNT = ceil(1300 ns * 100 MHz) IC_LCNTSCL PERIOD = 130
Actual MIN_SCL_HIGHTime = 60*(1/100 MHz) = 600 ns
Actual MIN_SCL_LOWtime = 130*(1/100 MHz) = 1300 ns †

```

21.4.6. SDA Hold Time

The I²C protocol specification requires 300 ns of hold time on the SDA signal in standard and fast speed modes. Board delays on the SCL and SDA signals can mean that the hold time requirement is met at the I²C master, but not at the I²C slave (or vice-versa). As each application encounters differing board delays, the I²C controller contains a software programmable register, `IC_SDA_HOLD`, to enable dynamic adjustment of the SDA hold time. `IC_SDA_HOLD` effects both slave-transmitter and master mode.

21.4.7. DMA Controller Interface

The I²C controller supports DMA signaling to indicate when data is ready to be read or when the transmit FIFO needs data. This support requires 2 DMA channels, one for transmit data and one for receive data. The I²C controller supports both single and burst DMA transfers. System software can choose the DMA burst mode by programming an appropriate value into the threshold registers. The recommended setting of the FIFO threshold register value is half full.

To enable the DMA controller interface on the I²C controller, you must write to the DMA control register (`DMACR`) bits. Writing a 1 into the `TDMAE` bit field of `DMACR` register enables the I²C controller transmit handshaking interface. Writing a 1 into the `RDMAE` bit field of the `DMACR` register enables the I²C controller receive handshaking interface. †

Related Information

[DMA Controller](#) on page 1969

For details about the DMA burst length microcode setup, refer to the *DMA controller* chapter.

21.4.8. Clocks

Each I²C controller is connected to the `l4_sp_clk` clock, which clocks transfers in standard and fast mode. The clock input is driven by the clock manager.

Related Information

[Clock Manager](#) on page 56

For more information, refer to *Clock Manager* chapter.

21.4.9. Resets

Each I²C controller has a separate reset signal. The reset manager drives the signals on a cold or warm reset.

Related Information

[Reset Manager](#) on page 138

For more information, refer to *Reset Manager* chapter.

21.4.9.1. Taking the I²C Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

21.5. I²C Controller Programming Model

This section describes the programming model for the I²C controllers based on the two master and slave operation modes. †

Note: Each I²C controller should be set to operate only as an I²C master or as an I²C slave, never set both simultaneously. Ensure that bit 6 (`IC_SLAVE_DISABLE`) and 0 (`IC_MASTER_MODE`) of the `IC_CON` register are never set to 0 and 1, respectively. †

21.5.1. Slave Mode Operation

21.5.1.1. Initial Configuration

To use the I²C controller as a slave, perform the following steps: †

1. Disable the I²C controller by writing a 0 to bit 0 of the `IC_ENABLE` register. †
2. Write to the `IC_SAR` register (bits 9:0) to set the slave address. This is the address to which the I²C controller responds. †

Note: The reset value for the I²C controller slave address is 0x55. If you are using 0x55 as the slave address, you can safely skip this step.

3. Write to the IC_CON register to specify which type of addressing is supported (7- or 10-bit by setting bit 3). Enable the I²C controller in slave-only mode by writing a 0 into bit 6 (IC_SLAVE_DISABLE) and a 0 to bit 0 (MASTER_MODE). †

Note: Slaves and masters do not have to be programmed with the same type of addressing 7- or 10-bit address. For instance, a slave can be programmed with 7-bit addressing and a master with 10-bit addressing, and vice versa. †

4. Enable the I²C controller by writing a 1 in bit 0 of the IC_ENABLE register. †

Note: It is recommended that the I²C Slave be brought out of reset only when the I²C bus is IDLE. De-asserting the reset when a transfer is ongoing on the bus causes internal flip-flops used to synchronize SDA and SCL to toggle from a reset value of 1 to the actual value on the bus. In this scenario, if SDA toggling from 1 to 0 while SCL is 1, thereby causing a false START condition to be detected by the I²C Slave by configuring the I²C with IC_SLAVE_DISABLE = 1 and IC_MASTER_MODE = 1 so that the Slave interface is disabled after reset. It can then be enabled by programming IC_CON[0] = 0 and IC_CON[6] = 0 after the internal SDA and SCL have synchronized to the value on the bus; this takes approximately 6 ic_clk cycles after reset de-assertion. †

21.5.1.2. Slave-Transmitter Operation for a Single Byte

When another I²C master device on the bus addresses the I²C controller and requests data, the I²C controller acts as a slave-transmitter and the following steps occur: †

1. The other I²C master device initiates an I²C transfer with an address that matches the slave address in the IC_SAR register of the I²C controller †
2. The I²C controller acknowledges the sent address and recognizes the direction of the transfer to indicate that it is acting as a slave-transmitter. †
3. The I²C controller asserts the RD_REQ interrupt (bit 5 of the IC_RAW_INTR_STAT register) and waits for software to respond. †

If the RD_REQ interrupt has been masked, due to bit 5 of the IC_INTR_MASK register (M_RD_REQ bit field) being set to 0, then it is recommended that you instruct the CPU to perform periodic reads of the IC_RAW_INTR_STAT register. †

- Reads that indicate bit 5 of the IC_RAW_INTR_STAT register (R_RD_REQ bit field) being set to 1 must be treated as the equivalent of the RD_REQ interrupt being asserted. †
- Software must then act to satisfy the I²C transfer. †
- The timing interval used should be in the order of 10 times the fastest SCL clock period the I²C controller can handle. For example, for 400 Kbps, the timing interval is 25 us. †

Note: The value of 10 is recommended here because this is approximately the amount of time required for a single byte of data transferred on the I²C bus. †

4. If there is any data remaining in the TX FIFO before receiving the read request, the I²C controller asserts a TX_ABRT interrupt (bit 6 of the IC_RAW_INTR_STAT register) to flush the old data from the TX FIFO. †

Note: Because the I²C controller's TX FIFO is forced into a flushed/reset state whenever a TX_ABRT event occurs, it is necessary for software to release the I²C controller from this state by reading the IC_CLR_TX_ABRT register before attempting to write into the TX FIFO. For more information, refer to the C_RAW_INTR_STAT register description in the register map.†

If the TX_ABRT interrupt has been masked, due to of IC_INTR_MASK[6] register (M_TX_ABRT bit field) being set to 0, then it is recommended that the CPU performs periodic reads of the IC_RAW_INTR_STAT register. †

- Reads that indicate bit 6 (R_TX_ABRT) being set to 1 must be treated as the equivalent of the TX_ABRT interrupt being asserted. †
 - There is no further action required from software. †
 - The timing interval used should be similar to that described in the previous step for the IC_RAW_INTR_STAT[5] register. †
5. Software writes to the DAT bits of the IC_DATA_CMD register with the data to be written and writes a 0 in bit 8.†
 6. Software must clear the RD_REQ and TX_ABRT interrupts (bits 5 and 6, respectively) of the IC_RAW_INTR_STAT register before proceeding. †
- If the RD_REQ and/or TX_ABRT interrupts have been masked, then clearing of the IC_RAW_INTR_STAT register will have already been performed when either the R_RD_REQ or R_TX_ABRT bit has been read as 1. †
7. The I²C controller transmits the byte. †
 8. The master may hold the I²C bus by issuing a RESTART condition or release the bus by issuing a STOP condition. †

21.5.1.3. Slave-Receiver Operation for a Single Byte

When another I²C master device on the bus addresses the I²C controller and is sending data, the I²C controller acts as a slave-receiver and the following steps occur:†

1. The other I²C master device initiates an I²C transfer with an address that matches the I²C controller's slave address in the IC_SAR register. †
2. The I²C controller acknowledges the sent address and recognizes the direction of the transfer to indicate that the I²C controller is acting as a slave-receiver. †
3. I²C controller receives the transmitted byte and places it in the receive buffer. †

Note: If the RX FIFO is completely filled with data when a byte is pushed, then an overflow occurs and the I²C controller continues with subsequent I²C transfers. Because a NACK is not generated, software must recognize the overflow when indicated by the I²C controller (by the R_RX_OVER bit in the IC_INTR_STAT register) and take appropriate actions to recover from lost data. Hence, there is a real time constraint on software to service the RX FIFO before the latter overflow as there is no way to reapply pressure to the remote transmitting master. †

4. I²C controller asserts the RX_FULL interrupt (IC_RAW_INTR_STAT[2] register). †

If the `RX_FULL` interrupt has been masked, due to setting `IC_INTR_MASK[2]` register to 0 or setting `IC_TX_TL` to a value larger than 0, then it is recommended that the CPU does periodic reads of the `IC_STATUS` register. Reads of the `IC_STATUS` register, with bit 3 (`RFNE`) set at 1, must then be treated by software as the equivalent of the `RX_FULL` interrupt being asserted. †

5. Software may read the byte from the `IC_DATA_CMD` register (bits 7:0). †
6. The other master device may hold the I²C bus by issuing a RESTART condition or release the bus by issuing a STOP condition. †

21.5.1.4. Slave-Transfer Operation for Bulk Transfers

In the standard I²C protocol, all transactions are single byte transactions and the programmer responds to a remote master read request by writing one byte into the slave's TX FIFO. When a slave (slave-transmitter) is issued with a read request (`RD_REQ`) from the remote master (master-receiver), at a minimum there should be at least one entry placed into the slave-transmitter's TX FIFO. The I²C controller is designed to handle more data in the TX FIFO so that subsequent read requests can receive that data without raising an interrupt to request more data. Ultimately, this eliminates the possibility of significant latencies being incurred between raising the interrupt for data each time had there been a restriction of having only one entry placed in the TX FIFO. †

This mode only occurs when I²C controller is acting as a slave-transmitter. If the remote master acknowledges the data sent by the slave-transmitter and there is no data in the slave's TX FIFO, the I²C controller raises the read request interrupt (`RD_REQ`) and waits for data to be written into the TX FIFO before it can be sent to the remote master. †

If the `RD_REQ` interrupt is masked, due to bit 5 (`M_RD_REQ`) of the `IC_INTR_STAT` register being set to 0, then it is recommended that the CPU does periodic reads of the `IC_RAW_INTR_STAT` register. Reads of `IC_RAW_INTR_STAT` that return bit 5 (`R_RD_REQ`) set to 1 must be treated as the equivalent of the `RD_REQ` interrupt referred to in this section.†

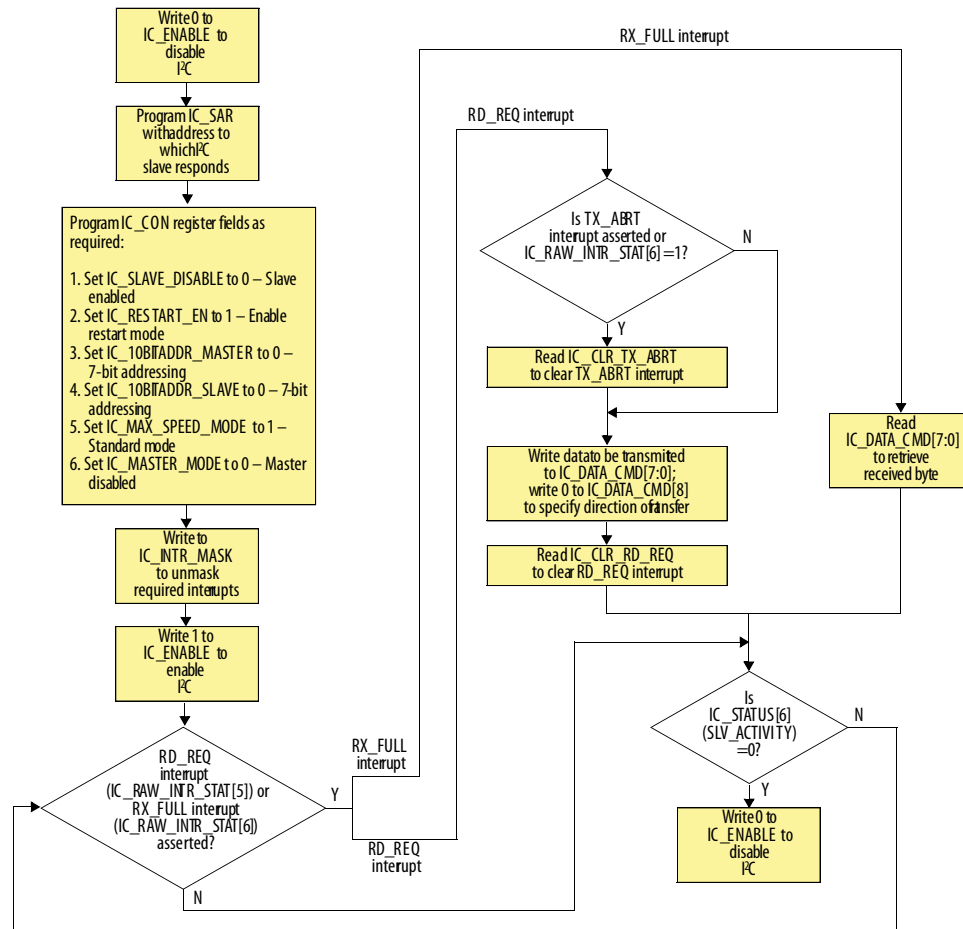

The `RD_REQ` interrupt is raised upon a read request, and like interrupts, must be cleared when exiting the interrupt service handling routine (ISR). The ISR allows you to either write 1 byte or more than 1 byte into the TX FIFO. During the transmission of these bytes to the master, if the master acknowledges the last byte then the slave must raise the `RD_REQ` again because the master is requesting for more data. †

If the programmer knows in advance that the remote master is requesting a packet of *n* bytes, then when another master addresses the I²C controller and requests data, the TX FIFO could be written with *n* number bytes and the remote master receives it as a continuous stream of data. For example, the I²C controller slave continues to send data to the remote master as long as the remote master is acknowledging the data sent and there is data available in the TX FIFO. There is no need to issue `RD_REQ` again. †

If the remote master is to receive *n* bytes from the I²C controller but the programmer wrote a number of bytes larger than *n* to the TX FIFO, then when the slave finishes sending the requested *n* bytes, it clears the TX FIFO and ignores any excess bytes. †

The I²C controller generates a transmit abort (TX_ABORT) event to indicate the clearing of the TX FIFO in this example. At the time an ACK/NACK is expected, if a NACK is received, then the remote master has all the data it wants. At this time, a flag is raised within the slave's state machine to clear the leftover data in the TX FIFO. This flag is transferred to the processor bus clock domain where the FIFO exists and the contents of the TX FIFO are cleared at that time. †

21.5.1.5. Slave Programming Model

21.5.2. Master Mode Operation

21.5.2.1. Initial Configuration

For master mode operation, the target address and address format can be changed dynamically without having to disable the I²C controller. This feature is only applicable when the I²C controller is acting as a master because the slave requires the component to be disabled before any changes can be made to the address. To use the I²C controller as a master, perform the following steps: †

For multiple I²C transfers, perform additional writes to the Tx FIFO such that the Tx FIFO does not become empty during the I²C transaction. If the Tx FIFO is completely emptied at any stage, then the master stalls the transfer by holding the SCL line low because there was no stop bit indicating the master to issue a STOP. The master will complete the transfer when it finds a Tx FIFO entry tagged with a Stop bit.

1. Disable the I²C controller by writing 0 to bit 0 of the IC_ENABLE register. †
2. Write to the IC_CON register to set the maximum speed mode supported for slave operation (bits 2:1) and to specify whether the I²C controller starts its transfers in 7/10 bit addressing mode when the device is a slave (bit 3). †
3. Write to the IC_TAR register the address of the I²C device to be addressed. It also indicates whether a General Call or a START BYTE command is going to be performed by I²C. The desired speed of the I²C controller master-initiated transfers, either 7-bit or 10-bit addressing, is controlled by the IC_10BITADDR_MASTER bit field (bit 12). †
4. Enable the I²C controller by writing a 1 in bit 0 of the IC_ENABLE register. †
5. Now write the transfer direction and data to be sent to the IC_DATA_CMD register. If the IC_DATA_CMD register is written before the I²C controller is enabled, the data and commands are lost as the buffers are kept cleared when the I²C controller is not enabled. †

21.5.2.2. Dynamic IC_TAR or IC_10BITADDR_MASTER Update

The I²C controller supports dynamic updating of the IC_TAR (bits 9:0) and IC_10BITADDR_MASTER (bit 12) bit fields of the IC_TAR register. You can dynamically write to the IC_TAR register provided the following conditions are met: †

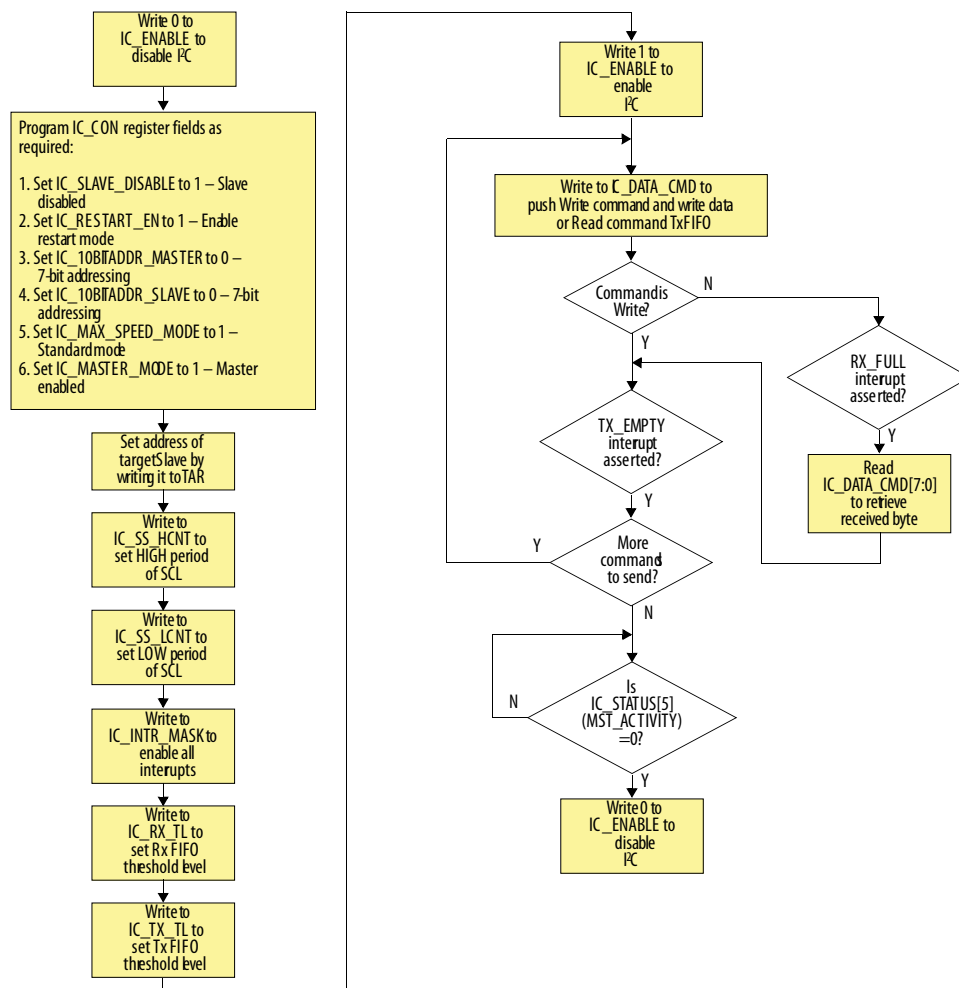

- The I²C controller is not enabled (IC_ENABLE=0); †
- The I²C controller is enabled (IC_ENABLE=1); AND I²C controller is NOT engaged in any Master (TX, RX) operation (IC_STATUS[5]=0); AND I²C controller is enabled to operate in Master mode (IC_CON[0]=1); AND there are no entries in the TX FIFO (IC_STATUS[2]=1) †

21.5.2.3. Master Transmit and Master Receive

The I²C controller supports switching back and forth between reading and writing dynamically. To transmit data, write the data to be written to the lower byte of the I²C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD). The CMD bit [8] should be written to 0 for I²C write operations. Subsequently, a read command may be issued by writing "don't cares" to the lower byte of the IC_DATA_CMD register, and a 1 should be written to the CMD bit.†

21.5.2.4. Master Programming Model

21.5.3. Disabling the I²C Controller

The register `IC_ENABLE_STATUS` is added to allow software to unambiguously determine when the hardware has completely shutdown in response to the `IC_ENABLE` register being set from 1 to 0. †

1. Define a timer interval (`ti2c_poll`) equal to the 10 times the signaling period for the highest I²C transfer speed used in the system and supported by the I²C controller. For example, if the highest I²C transfer mode is 400 Kbps, then `ti2c_poll` is 25 us. †
2. Define a maximum time-out parameter, `MAX_T_POLL_COUNT`, such that if any repeated polling operation exceeds this maximum value, an error is reported. †
3. Execute a blocking thread/process/function that prevents any further I²C master transactions to be started by software, but allows any pending transfers to be completed.

- This step can be ignored if the I²C controller is programmed to operate as an I²C slave only. †
- 4. The variable `POLL_COUNT` is initialized to zero. †
- 5. Set `IC_ENABLE` to 0. †
- 6. Read the `IC_ENABLE_STATUS` register and test the `IC_EN` bit (bit 0). Increment `POLL_COUNT` by one. If `POLL_COUNT` \geq `MAX_T_POLL_COUNT`, exit with the relevant error code. †
- 7. If `IC_ENABLE_STATUS[0]` is 1, then sleep for `ti2c_poll` and proceed to the previous step. Otherwise, exit with a relevant success code. †

21.5.4. Abort Transfer

The ABORT control bit of the `IC_ENABLE` register allows the software to relinquish the I²C bus before completing the issued transfer commands from the Tx FIFO. In response to an ABORT request, the controller issues the STOP condition over the I²C bus, followed by Tx FIFO flush. Aborting the transfer is allowed only in master mode of operation.†

1. Stop filling the Tx FIFO (`IC_DATA_CMD`) with new commands.†
2. When operating in DMA mode, disable the transmit DMA by setting `TDMAE` to 0. †
3. Set bit 1 of the `IC_ENABLE` register (ABORT) to 1.†
4. Wait for the `M_TX_ABRT` interrupt.†
5. Read the `IC_TX_ABRT_SOURCE` register to identify the source as `ABRT_USER_ABRT`.†

21.5.5. DMA Controller Operation

To enable the DMA controller interface on the I²C controller, you must write the DMA Control Register (`IC_DMA_CR`). Writing a 1 to the `TDMAE` bit field of `IC_DMA_CR` register enables the I²C controller transmit handshaking interface. Writing a 1 to the `RDMAE` bit field of the `IC_DMA_CR` register enables the I²C controller receive handshaking interface.†

The FIFO buffer depth (`FIFO_DEPTH`) for both the RX and TX buffers in the I²C controller is 64 entries.

Related Information

[DMA Controller](#) on page 1969

For details about the DMA burst length microcode setup, refer to the *DMA controller* chapter.

21.5.5.1. Transmit FIFO Underflow

During I²C serial transfers, transmit FIFO requests are made to the DMA controller whenever the number of entries in the transmit FIFO is less than or equal to the value in DMA Transmit Data Level Register (`IC_DMA_TDLR`), also known as the watermark level. The DMA controller responds by writing a burst of data to the transmit FIFO buffer, of length specified as DMA burst length. †

Note: Data should be fetched from the DMA often enough for the transmit FIFO to perform serial transfers continuously, that is, when the FIFO begins to empty, another DMA request should be triggered. Otherwise, the FIFO will run out of the data (underflow) causing the master to stall the transfer by holding the SCL line low. To prevent this condition, you must set the watermark level correctly.†

Related Information

DMA Controller on page 1969

For details about the DMA burst length microcode setup, refer to the *DMA controller* chapter.

21.5.5.2. Transmit Watermark Level

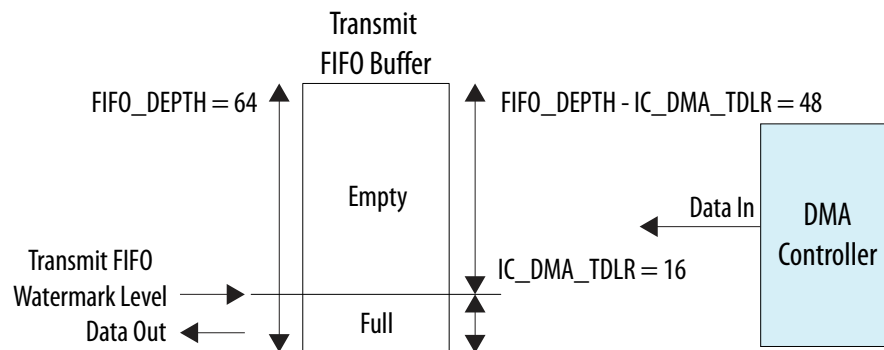

Consider the example where the assumption is made: †

DMA burst length = FIFO_DEPTH - IC_DMA_TDLR †

Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO. Consider the following two different watermark level settings: †

- Case 1: IC_DMA_TDLR = 16: †
 - Transmit FIFO watermark level = IC_DMA_TDLR = 16: †
 - DMA burst length = FIFO_DEPTH - IC_DMA_TDLR = 48: †
 - I²C transmit FIFO_DEPTH = 64: †
 - Block transaction size = 240: †

Figure 171. Transmit FIFO Watermark Level = 16

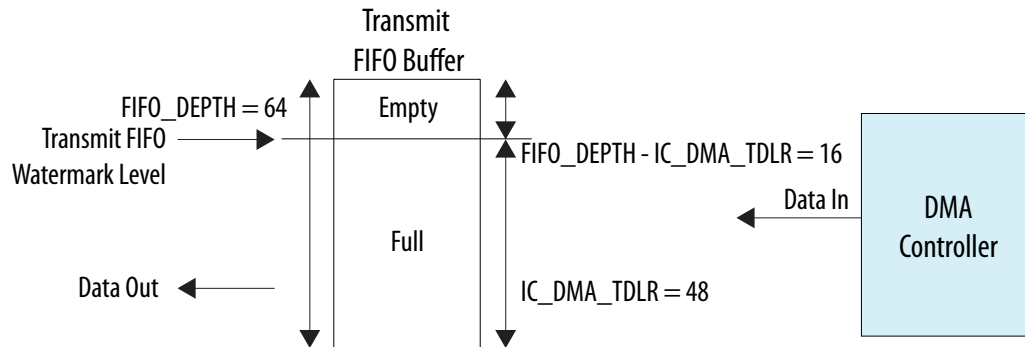

The number of burst transactions needed equals the block size divided by the number of data items per burst:

$$\text{Block transaction size/DMA burst length} = 240/48 = 5$$

The number of burst transactions in the DMA block transfer is 5. But the watermark level, IC_DMA_TDLR, is quite low. Therefore, the probability of transmit underflow is high where the I²C serial transmit line needs to transmit data, but there is no data left in the transmit FIFO. This occurs because the DMA has not had time to service the DMA request before the FIFO becomes empty.

- Case 2: $IC_DMA_TDLR = 48$ †
 - Transmit FIFO watermark level = $IC_DMA_TDLR = 48$ †
 - DMA burst length = $FIFO_DEPTH - IC_DMA_TDLR = 16$ †
 - I²C transmit $FIFO_DEPTH = 64$ †
 - Block transaction size = 240 †

Figure 172. Transmit FIFO Watermark Level = 48

Number of burst transactions in block: †

Block transaction size/DMA burst length = $240/16 = 15$ †

In this block transfer, there are 15 destination burst transactions in a DMA block transfer. But the watermark level, IC_DMA_TDLR , is high. Therefore, the probability of I²C transmit underflow is low because the DMA controller has plenty of time to service the destination burst transaction request before the I²C transmit FIFO becomes empty. †

Thus, the second case has a lower probability of underflow at the expense of more burst transactions per block. This provides a potentially greater amount of bursts per block and worse bus utilization than the former case. †

Therefore, the goal in choosing a watermark level is to minimize the number of transactions per block, while at the same time keeping the probability of an underflow condition to an acceptable level. In practice, this is a function of the ratio of the rate at which the I²C transmits data to the rate at which the DMA can respond to destination burst requests. †

21.5.5.3. Transmit FIFO Overflow

Setting the DMA burst length to a value greater than the watermark level that triggers the DMA request might cause overflow when there is not enough space in the transmit FIFO to service the destination burst request. Therefore, the following equation must be adhered to in order to avoid overflow: †

$$DMA \text{ burst length} \leq FIFO_DEPTH - IC_DMA_TDLR$$

In case 2: $IC_DMA_TDLR = 48$, the amount of space in the transmit FIFO at the time of the burst request is made is equal to the DMA burst length. Thus, the transmit FIFO may be full, but not overflowed, at the completion of the burst transaction. †

Therefore, for optimal operation, DMA burst length should be set at the FIFO level that triggers a transmit DMA request; that is: †

$$\text{DMA burst length} = \text{FIFO_DEPTH} - \text{IC_DMA_TDLR}$$

Adhering to this equation reduces the number of DMA bursts needed for block transfer, and this in turn improves bus utilization. †

The transmit FIFO will not be full at the end of a DMA burst transfer if the I²C controller has successfully transmitted one data item or more on the I²C serial transmit line during the transfer. †

21.5.5.4. Receive FIFO Overflow

During I²C serial transfers, receive FIFO requests are made to the DMA whenever the number of entries in the receive FIFO is at or above the DMA Receive Data Level Register, that is $\text{IC_DMA_RDLR} + 1$. This is known as the watermark level. The DMA responds by fetching a burst of data from the receive FIFO. †

Data should be fetched by the DMA often enough for the receive FIFO to accept serial transfers continuously, that is, when the FIFO begins to fill, another DMA transfer is requested. Otherwise the FIFO will fill with data (overflow). To prevent this condition, the user must set the watermark level correctly. †

21.5.5.5. Receive Watermark Level

Similar to choosing the transmit watermark level described earlier, the receive watermark level, $\text{IC_DMA_RDLR} + 1$, should be set to minimize the probability of overflow, as shown in the Receive FIFO Buffer diagram. It is a trade off between the number of DMA burst transactions required per block versus the probability of an overflow occurring. †

21.5.5.6. Receive FIFO Underflow

Setting the source transaction burst length greater than the watermark level can cause underflow where there is not enough data to service the source burst request. Therefore, the following equation must be adhered to avoid underflow: †

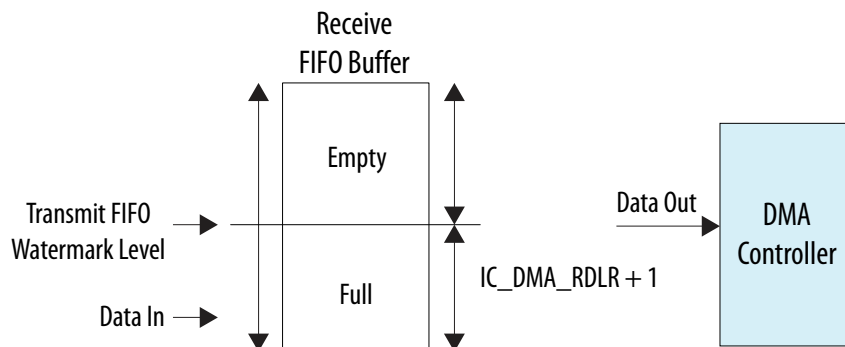

$$\text{DMA burst length} = \text{IC_DMA_RDLR} + 1$$

If the number of data items in the receive FIFO is equal to the source burst length at the time of the burst request is made, the receive FIFO may be emptied, but not underflowed, at the completion of the burst transaction. For optimal operation, DMA burst length should be set at the watermark level, $\text{IC_DMA_RDLR} + 1$. †

Adhering to this equation reduces the number of DMA bursts in a block transfer, which in turn can avoid underflow and improve bus utilization. †

Note: The receive FIFO will not be empty at the end of the source burst transaction if the I²C controller has successfully received one data item or more on the I²C serial receive line during the burst. †

Figure 173. Receive FIFO Buffer

21.6. I²C Controller Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the [Arria 10 HPS Address Map and Register Definitions](#).

21.6.1. i2c Address Map

Module Instance	Base Address	End Address
i_i2c_0_i2c	0xFFC02200	0xFFC022FF
i_i2c_1_i2c	0xFFC02300	0xFFC023FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

21.6.1.2. ic_con

I2C Control Register. This register can be written only when the IC_ENABLE[0] register is set to 0. Writes at other times have no effect.

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC02200
i_i2c_1_i2c	0xFFC02300	0xFFC02300

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

ic_con Fields

Bit	Name	Description	Access	Reset
31:9	rsvd_ic_con_31to9	Reserved bits [31:9] - Read Only	RO	0x0
8	tx_empty_ctrl	This bit controls the generation of the TX_EMPTY interrupt, as described in the IC_RAW_INTR_STAT register. Reset value: 0x0.	RW	0x0

continued...

Bit	Name	Description	Access	Reset						
7	stop_det_ifaddressed	<p>In slave mode: 1: issues the STOP_DET interrupt only when it is addressed. 0: issues the STOP_DET irrespective of whether it's addressed or not. Dependencies: This register bit value is applicable in the slave mode only (MASTER_MODE = 1'b0) Reset value: 0x0 NOTE: During a general call address, this slave does not issue the STOP_DET interrupt if STOP_DET_IF_ADDRESSED = 1'b1, even if the slave responds to the general call address by generating ACK. The STOP_DET interrupt is generated only when the transmitted address matches the slave address (SAR).</p>	RW	0x0						
6	ic_slave_disable	<p>This bit controls whether I2C has its slave disabled. Once the preseln signal is applied, then this bit is set to 1. When this bit is set (slave is disabled), the I2C module functions only as a master and does not perform any action that requires a slave. 0: slave is enabled 1: slave is disabled</p> <p>NOTE: Software should ensure that if this bit is written with 0, then bit 0 should also be written with a 0.</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>ENABLE</td></tr><tr><td>0x1</td><td>DISABLE</td></tr></table>	Value	Description	0x0	ENABLE	0x1	DISABLE	RW	0x1
Value	Description									
0x0	ENABLE									
0x1	DISABLE									
5	ic_restart_en	<p>Determines whether RESTART conditions may be sent when acting as a master. Some older slaves do not support handling RESTART conditions; however, RESTART conditions are used in several DW_apb_i2c operations. 0: disable 1: enable When RESTART is disabled, the master is prohibited from performing the following functions: - Change direction within a transfer (split) - Send a START BYTE - High-speed mode operation - Combined format transfers in 7-bit addressing modes - Read operation with a 10-bit address - Send multiple bytes per transfer By replacing RESTART condition followed by a STOP and a subsequent START condition, split operations are broken down into multiple I2C transfers. If the above operations are performed, it will result in setting bit 6 (TX_ABRT) of the IC_RAW_INTR_STAT register. Reset value: 0x1</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>DISABLE</td></tr><tr><td>0x1</td><td>ENABLE</td></tr></table>	Value	Description	0x0	DISABLE	0x1	ENABLE	RW	0x1

21.6.1.3. ic_tar

Name: I2C Target Address Register

All bits can be dynamically updated as long as any set of the following conditions are true:

- The I2C is NOT enabled (IC_ENABLE[0] is set to 0);
or
- The I2C is enabled (IC_ENABLE[0]=1);
AND
the I2C is NOT engaged in any Master (tx, rx) operation (IC_STATUS[5]=0);
AND
I2C is enabled to operate in Master mode (IC_CON[0]=1);
AND
there are NO entries in the TX FIFO (IC_STATUS[2]=1)

Module Instance	Base Address	Register Address

Bit	Name	Description	Access	Reset						
		bus until a new command is available in the Tx FIFO. Reset value: 0x0								
8	cmd	<p>This bit controls whether a read or a write is performed. This bit does not control the direction when the I2C acts as a slave. It controls only the direction when it acts as a master. 1 = Read 0 = Write When a command is entered in the TX FIFO, this bit distinguishes the write and read commands. In slave-receiver mode, this bit is a 'don't care' because writes to this register are not required. In slave-transmitter mode, a '0' indicates that CPU data is to be transmitted and as DAT or IC_DATA_CMD[7:0]. When programming this bit, you should remember the following: attempting to perform a read operation after a General Call command has been sent results in a TX_ABORT interrupt (bit 6 of the IC_RAW_INTR_STAT register), unless bit 11 (SPECIAL) in the IC_TAR register has been cleared. If a '1' is written to this bit after receiving a RD_REQ interrupt, then a TX_ABORT interrupt occurs. NOTE: It is possible that while attempting a master I2C read transfer, a RD_REQ interrupt may have occurred simultaneously due to a remote I2C master addressing the I2C module. In this type of scenario, the I2C module ignores the IC_DATA_CMD write, generates a TX_ABORT interrupt, and waits to service the RD_REQ interrupt. Reset value: 0x0</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>WR</td></tr><tr><td>0x1</td><td>RD</td></tr></table>	Value	Description	0x0	WR	0x1	RD	WO	0x0

ic_intr_stat Fields

Bit	Name	Description	Access	Reset
13	r_master_on_hold	Indicates whether master is holding the bus and TX FIFO is empty. Reset value: 0x0	RO	0x0
12	r_restart_det	Indicates a RESTART condition has occurred on the I2C interface when the I2C module is operating in slave mode and addressed. Reset value: 0x0	RO	0x0
11	r_gen_call	Set only when a General Call address is received and it is acknowledged. It stays set until it is cleared either by disabling the I2C or when the CPU reads bit 0 of the IC_CLR_GEN_CALL register. The I2C stores the received data in the Rx buffer. Reset value: 0x0	RO	0x0
10	r_start_det	Indicates whether a START or RESTART condition has occurred on the I2C interface regardless of whether the I2C is operating in slave or master mode. Reset value: 0x0	RO	0x0
9	r_stop_det	The behavior of the STOP_DET interrupt status differs based on the STOP_DET_IFADDRESSED selection in the IC_CON register When STOP_DET_IFADDRESSED = 0 : Indicates whether a STOP condition has occurred on the I2C interface regardless of whether DW_apb_i2c is operating in slave or master mode. In slave mode, a STOP_DET interrupt is generated irrespective of whether the slave is addressed or not. When STOP_DET_IFADDRESSED = 1 : In Master Mode (MASTER_MODE = 1'b1), indicates a STOP condition has occurred on the I2C interface. In Slave Mode (MASTER_MODE = 1'b0), STOP_DET interrupt is generated only if the slave is addressed. NOTE: During a general call address, this slave does not issue a STOP_DET interrupt if STOP_DET_IFADDRESSED=1'b1, even if the slave responds to the general call address by generating ACK. The STOP_DET interrupt is generated only when the transmitted address matches the slave address (SAR). Reset value: 0x0	RO	0x0
8	r_activity	This bit captures the I2C activity and stays set until it is cleared. There are four ways to clear it: - Disabling the I2C module - Reading the IC_CLR_ACTIVITY register - Reading the IC_CLR_INTR register - System reset Once this bit is set, it stays set unless one of the four methods is used to clear it. Even if the I2C module is idle, this bit remains set until cleared, indicating that there was activity on the bus. Reset value: 0x0	RO	0x0
continued...				

Bit	Name	Description	Access	Reset
7	r_rx_done	When the I2C module is acting as a slave-transmitter, this bit is set to 1 if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done. Reset value: 0x0	RO	0x0
6	r_tx_abrt	This bit indicates if the I2C module, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'. When this bit is set to 1, the IC_TX_ABORT_SOURCE register indicates the reason why the transmit abort takes places. NOTE: The I2C flushes/resets/empties the TX FIFO whenever this bit is set. The TX FIFO remains in this flushed state until the register IC_CLR_TX_ABORT is read. Once this read is performed, the TX FIFO is then ready to accept more data bytes from the APB interface. Reset value: 0x0	RO	0x0
5	r_rd_req	This bit is set to 1 when the I2C module is acting as a slave and another I2C master is attempting to read data from it. The I2C module holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the IC_DATA_CMD register. This bit is set to 0 just after the processor reads the IC_CLR_RD_REQ register. Reset value: 0x0	RO	0x0
4	r_tx_empty	The behavior of the TX_EMPTY interrupt status differs based on the TX_EMPTY_CTRL selection in the IC_CON register. When TX_EMPTY_CTRL = 0: This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register. When TX_EMPTY_CTRL = 1: This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register and the transmission of the address/data from the internal shift register for the most recently popped command is completed. It is automatically cleared by hardware when the buffer level goes above the threshold. When IC_ENABLE[0] is set to 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer any activity, then with ic_en=0, this bit is set to 0. Reset value: 0x0	RO	0x0
3	r_tx_over	Set during transmit if the transmit buffer is filled to IC_TX_BUFFER_DEPTH and the processor attempts to issue another I2C command by writing to the IC_DATA_CMD register. When the module is disabled, this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0
continued...				

Bit	Name	Description	Access	Reset
2	r_rx_full	Set when the receive buffer reaches or goes above the RX_TL threshold in the IC_RX_TL register. It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled (IC_ENABLE[0]=0), the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the IC_ENABLE bit 0 is programmed with a 0, regardless of the activity that continues. Reset value: 0x0	RO	0x0
1	r_rx_over	Set if the receive buffer is completely filled to the Rx buffer depth of 64 and an additional byte is received from an external I2C device. The I2C acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0
0	r_rx_under	Set if the processor attempts to read the receive buffer when it is empty by reading from the IC_DATA_CMD register. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0

21.6.1.11. ic_intr_mask

Name: I2C Interrupt Mask Register

These bits mask their corresponding interrupt status bits. They are active high; a value of 0 prevents a bit from generating an interrupt.

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC02230

Bit	Name	Description	Access	Reset
13	master_on_hold	Indicates whether master is holding the bus and TX FIFO is empty. Reset value: 0x0	RO	0x0
12	restart_det	Indicates whether a RESTART condition has occurred on the I2C interface when it is operating in Slave mode and the slave is being addressed. (Note: Following are exceptions where the Restart interrupt will not get generated. In the case of a Startbyte transfer, where the Restart comes before the Address field as per the I2C protocol defined format, the Slave is still not in the addressed mode and hence will not generate the RESTART_DET interrupt.) Reset value: 0x0	RO	0x0
11	gen_call	Set only when a General Call address is received and it is acknowledged. It stays set until it is cleared either by disabling the I2C or when the CPU reads bit 0 of the IC_CLR_GEN_CALL register. The I2C stores the received data in the Rx buffer. Reset value: 0x0	RO	0x0
10	start_det	Indicates whether a START or RESTART condition has occurred on the I2C interface regardless of whether the I2C is operating in slave or master mode. Reset value: 0x0	RO	0x0
9	stop_det	The behavior of the STOP_DET interrupt status differs based on the STOP_DET_IFADDRESSED selection in the IC_CON register When STOP_DET_IFADDRESSED = 0 Indicates whether a STOP condition has occurred on the I2C interface regardless of whether the I2C module is operating in slave or master mode. In slave mode, a STOP_DET interrupt is generated irrespective of whether the slave is addressed or not. When STOP_DET_IFADDRESSED = 1 In Master Mode (MASTER_MODE = 1), indicates a STOP condition has occurred on the I2C interface. In Slave Mode (MASTER_MODE = 0), a STOP_DET interrupt is generated only if the slave is addressed. NOTE: During a general call address, this slave does not issue a STOP_DET interrupt if STOP_DET_IFADDRESSED=1, even if the slave responds to the general call address by generating ACK. The STOP_DET interrupt is generated only when the transmitted address matches the slave address (SAR). Reset value: 0x0.	RO	0x0
8	activity	This bit captures the I2C activity and stays set until it is cleared. There are four ways to clear it: - Disabling the I2C module - Reading the IC_CLR_ACTIVITY register - Reading the IC_CLR_INTR register - System reset Once this bit is set, it stays set unless one of the four methods is used to clear it.	RO	0x0

continued...

Bit	Name	Description	Access	Reset
		Even if the the I2C module is idle, this bit remains set until cleared, indicating that there was activity on the bus. Reset value: 0x0		
7	rx_done	When the I2C is acting as a slave-transmitter, this bit is set to 1 if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done. Reset value: 0x0	RO	0x0
6	tx_abrt	This bit indicates if the I2C, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'. When this bit is set to 1, the IC_TX_ABRT_SOURCE register indicates the reason why the transmit abort takes places. NOTE: The I2C flushes/resets/empties the TX FIFO whenever this bit is set. The TX FIFO remains in this flushed state until the register IC_CLR_TX_ABRT is read. Once this read is performed, the TX FIFO is then ready to accept more data bytes from the APB interface. Reset value: 0x0	RO	0x0
5	rd_req	This bit is set to 1 when the I2C is acting as a slave and another I2C master is attempting to read data from it. The HPS I2C holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the IC_DATA_CMD register. This bit is set to 0 just after the processor reads the IC_CLR_RD_REQ register. Reset value: 0x0	RO	0x0
4	tx_empty	The behavior of the TX_EMPTY interrupt status differs based on the TX_EMPTY_CTRL selection in the IC_CON register. When TX_EMPTY_CTRL = 0: This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register. When TX_EMPTY_CTRL = 1: This bit is set to 1 when the transmit buffer is at or below the threshold value. set in the IC_TX_TL register and the transmission of the address/data from the internal shift register for the most recently popped command is completed. It is automatically cleared by hardware when the buffer level goes above the threshold. When IC_ENABLE[0] is set to 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer any activity, then with ic_en=0, this bit is set to 0. Reset value: 0x0.	RO	0x0
3	tx_over	Set during transmit if the transmit buffer is filled to its maximum TxFIFO buffer depth (64) and the processor attempts to issue another I2C command by writing to the	RO	0x0
continued...				

Bit	Name	Description	Access	Reset
		IC_DATA_CMD register. When the module is disabled, this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0		
2	rx_full	Set when the receive buffer reaches or goes above the RX_TL threshold in the IC_RX_TL register. It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled (IC_ENABLE[0]=0), the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the IC_ENABLE bit 0 is programmed with a 0, regardless of the activity that continues. Reset value: 0x0	RO	0x0
1	rx_over	Set if the receive buffer is completely filled to its maximum RxFIFO depth (64) and an additional byte is received from an external I2C device. The HPS I2C acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0
0	rx_under	Set if the processor attempts to read the receive buffer when it is empty by reading from the IC_DATA_CMD register. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0

21.6.1.13. ic_rx_tl

21.6.1.27. ic_status

Name: I2C Status Register

This is a read-only register used to indicate the current transfer status and FIFO status. The status register may be read at any time. None of the bits in this register request an interrupt.

When the I2C is disabled by writing 0 in bit 0 of the IC_ENABLE register:

- Bits 1 and 2 are set to 1
- Bits 3 and 4 are set to 0

When the master or slave state machines goes to idle and ic_en=0:

- Bits 5 and 6 are set to 0

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC02270
i_i2c_1_i2c	0xFFC02300	0xFFC02370

Offset: 0x70

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

21.6.1.28. ic_txflr

Name: I2C Transmit FIFO Level Register

This register contains the number of valid data entries in the transmit FIFO buffer. It is cleared whenever:

- The I2C is disabled
- There is a transmit abort that is, TX_ABRT bit is set in the IC_RAW_INTR_STAT register
- The slave bulk transmit mode is aborted

The register increments whenever data is placed into the transmit FIFO and decrements when data is taken from the transmit FIFO.

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC02274
i_i2c_1_i2c	0xFFC02300	0xFFC02374

Offset: 0x74

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved									txflr RO 0x0						

ic_txflr Fields

Bit	Name	Description	Access	Reset
6:0	txflr	Transmit FIFO Level. Contains the number of valid data entries in the transmit FIFO. Reset value: 0x0	RO	0x0

21.6.1.29. ic_rxflr

I2C Receive FIFO Level Register

This register contains the number of valid data entries in the receive FIFO buffer. It is cleared whenever:

- The I2C is disabled
- Whenever there is a transmit abort caused by any of the events tracked in IC_TX_ABRT_SOURCE

The register increments whenever data is placed into the receive FIFO and decrements when data is taken from the receive FIFO.

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC02278
i_i2c_1_i2c	0xFFC02300	0xFFC02378

Offset: 0x78

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ic_rxflr Fields

Bit	Name	Description	Access	Reset
6:0	rxflr	Receive FIFO Level. Contains the number of valid data entries in the receive FIFO. Reset value: 0x0	RO	0x0

21.6.1.30. ic_sda_hold

Name: I2C SDA Hold Time Length Register

The bits [15:0] of this register are used to control the hold time of SDA during transmit in both slave and master mode (after SCL goes from HIGH to LOW). The bits [23:16] of this register are used to extend the SDA transition (if any) whenever SCL is HIGH in the receiver in either master or slave mode. The values in this register are in units of ic_clk period. This register controls the amount of time delay. The relevant I2C requirement is thd:DAT as detailed in the I2C Bus Specification.

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC0227C
i_i2c_1_i2c	0xFFC02300	0xFFC0237C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved								ic_sda_rx_hold RW 0x0							
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ic_sda_tx_hold RW 0x1															

ic_sda_hold Fields

Bit	Name	Description	Access	Reset
23:16	ic_sda_rx_hold	Sets the required SDA hold time in units of ic_clk period, when the I2C module acts as a receiver.	RW	0x0
15:0	ic_sda_tx_hold	Sets the required SDA hold time in units of ic_clk period, when the I2C module acts as a transmitter.	RW	0x1

21.6.1.31. ic_tx_abrt_source

I2C Transmit Abort Source Register

This register has 32 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC02280
i_i2c_1_i2c	0xFFC02300	0xFFC02380

Offset: 0x80

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ic_tx_abrt_source Fields

Bit	Name	Description	Access	Reset
31:2 3	tx_flush_cnt	This field indicates the number of Tx FIFO Data Commands which are flushed due to TX_ABRT interrupt. It is cleared whenever I2C is disabled. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Slave-Transmitter	RO	0x0
22:1 7	rsvd_ic_tx_abrt_source_22to17	Reserved Reset value: 0x0	RO	0x0
16	abrt_user_abrt	This is a master-mode-only bit. Master has detected the transfer abort (IC_ENABLE[1]) Reset value: 0x0 Role of the I2C module: Master-Transmitter	RO	0x0
15	abrt_slvrd_intx	1: When the processor side responds to a slave mode request for data to be transmitted to a remote master and user writes a 1 in CMD (bit 8) of IC_DATA_CMD register. Reset value: 0x0 Role of I2C module: Slave-Transmitter	RO	0x0
14	abrt_slv_arblost	1: Slave lost the bus while transmitting data to a remote master. IC_TX_ABRT_SOURCE[12] is set at the same time. Note: Even though the slave never 'owns' the bus, something could go wrong on the bus. This is a fail safe check. For instance, during a data transmission at the low-to-high transition of SCL, if what is on the data bus is not what is supposed to be transmitted, then the I2C module no longer own the bus. Reset value: 0x0 Role of the I2C module: Slave-Transmitter	RO	0x0
13	abrt_slvflush_txfifo	1: Slave has received a read command and some data exists in the TX FIFO so the slave issues a TX_ABRT interrupt to flush old data in TX FIFO. Reset value: 0x0 Role of the I2C module: Slave-Transmitter	RO	0x0
12	arb_lost	1: Master has lost arbitration, or if IC_TX_ABRT_SOURCE[14] is also set, then the slave transmitter has lost arbitration. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Slave-Transmitter	RO	0x0
11	abrt_master_dis	1: User tries to initiate a Master operation with the Master mode disabled. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0
continued...				

Bit	Name	Description	Access	Reset
10	abrt_10b_rd_norstrt	1: The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) =0) and the master sends a read command in 10-bit addressing mode. Reset value: 0x0 Role of the I2C module: Master-Receiver	RO	0x0
9	abrt_sbyte_norstrt	To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; restart must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, bit 9 clears for one cycle and then gets reasserted. 1: The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) =0) and the user is trying to send a START Byte. Reset value: 0x0 Role of the I2C module: Master	RO	0x0
8	abrt_hs_norstrt	1: The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) =0) and the user is trying to use the master to transfer data in High Speed mode. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0
7	abrt_sbyte_ackdet	1: Master has sent a START Byte and the START Byte was acknowledged (wrong behavior). Reset value: 0x0 Role of the I2C module: Master	RO	0x0
6	abrt_hs_ackdet	1: Master is in High Speed mode and the High Speed Master code was acknowledged (wrong behavior). Reset value: 0x0 Role of the I2C module: Master	RO	0x0
5	abrt_gcall_read	1: DW_apb_i2c in master mode sent a General Call but the user programmed the byte following the General Call to be a read from the bus (IC_DATA_CMD[9] is set to 1). Reset value: 0x0 Role of the I2C module: Master-Transmitter	RO	0x0
4	abrt_gcall_noack	1: DW_apb_i2c in master mode sent a General Call and no slave on the bus acknowledged the General Call. Reset value: 0x0 Role of the I2C module: Master-Transmitter	RO	0x0
3	abrt_txdata_noack	1: This is a master-mode only bit. Master has received an acknowledgement for the address, but when it sent data byte(s) following the address, it did not receive an	RO	0x0
continued...				

Bit	Name	Description	Access	Reset
		acknowledge from the remote slave(s). Reset value: 0x0 Role of the I2C module: Master-Transmitter		
2	abrt_10addr2_noack	1: Master is in 10-bit address mode and the second address byte of the 10-bit address was not acknowledged by any slave. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0
1	abrt_10addr1_noack	1: Master is in 10-bit address mode and the first 10-bit address byte was not acknowledged by any slave. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0
0	abrt_7b_addr_noack	1: Master is in 7-bit addressing mode and the address sent was not acknowledged by any slave. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0

21.6.1.32. ic_slv_data_nack_only

Generate Slave Data NACK Register

The register is used to generate a NACK for the data part of a transfer when the I2C is acting as a slave-receiver.

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC02284
i_i2c_1_i2c	0xFFC02300	0xFFC02384

Offset: 0x84

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

ic_dma_rdlr Fields

Bit	Name	Description	Access	Reset
5:0	dmard1	Receive Data Level. This bit field controls the level at which a DMA request is made by the receive logic. The watermark level = DMARDL+1; that is, dma_rx_req is generated when the number	RW	0x0

Bit	Name	Description	Access	Reset
		of valid data entries in the receive FIFO is equal to or more than this field value + 1, and RDMAE =1. For instance, when DMARDL is 0, then dma_rx_req is asserted when 1 or more data entries are present in the receive FIFO. Reset value: 0x0		

21.6.1.36. ic_sda_setup

I2C SDA Setup Register

This register controls the amount of time delay (in terms of number of l4_sp_clk clock periods) introduced in the rising edge of SCL, relative to SDA changing, when the I2C module services a read request in a slave-transmitter operation. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification.

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC02294
i_i2c_1_i2c	0xFFC02300	0xFFC02394

Offset: 0x94

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	ack_gen_call	<div>ACK General Call. When set to 1, the I2C module responds with a ACK (by asserting ic_data_oe) when it receives a General Call. Otherwise, the I2C module responds with a NACK (by negating ic_data_oe). Default Reset value: 0x1</div> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0x0</td><td>NACK</td></tr><tr><td>0x1</td><td>ACK</td></tr></table>	Value	Description	0x0	NACK	0x1	ACK	RW	0x1
Value	Description									
0x0	NACK									
0x1	ACK									

21.6.1.38. ic_enable_status

I2C Enable Status Register

The register is used to report the I2C hardware status when the IC_ENABLE[0] register is set from 1 to 0; that is, when the I2C module is disabled. If IC_ENABLE[0] has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1. If IC_ENABLE[0] has been set to 0, bits 2:1 is only be valid as soon as bit 0 is read as '0'.
Note
When IC_ENABLE[0] has been written with '0' a delay occurs for bit 0 to be read as '0' because disabling the I2C module depends on I2C bus activities.

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC0229C
i_i2c_1_i2c	0xFFC02300	0xFFC0239C

													RO	RO	RO
													0x0	0x0	0x0

ic_enable_status Fields

Bit	Name	Description	Access	Reset
2	slv_rx_data_lost	Slave Received Data Lost. This bit indicates if a Slave-Receiver operation has been aborted with at least one data byte received from an I2C transfer due to the setting bit 0 of IC_ENABLE from 1 to 0. When read as 1, the I2C module is deemed to have been actively engaged in an aborted I2C transfer (with matching address) and the data phase of the I2C transfer has been entered, even though a data byte has been responded with a NACK. NOTE: If the remote I2C master terminates the transfer with a STOP condition before the I2C module has a chance to NACK a	RO	0x0

continued...

Bit	Name	Description	Access	Reset
		transfer, and IC_ENABLE[0] has been set to 0, then this bit is also set to 1. When read as 0, the I2C module is deemed to have been disabled without being actively involved in the data phase of a Slave-Receiver transfer. NOTE: The CPU can safely read this bit when IC_EN (bit 0) is read as 0. Reset value: 0x0		
1	slv_disabled_while_busy	Slave Disabled While Busy (Transmit, Receive). This bit indicates if a potential or active Slave operation has been aborted due to the setting bit 0 of the IC_ENABLE register from 1 to 0. This bit is set when the CPU writes a 0 to the IC_ENABLE register while: (a) The I2C is receiving the address byte of the Slave-Transmitter operation from a remote master; OR, (b) address and data bytes of the Slave-Receiver operation from a remote master. When read as 1, the I2C module is deemed to have forced a NACK during any part of an I2C transfer, irrespective of whether the I2C address matches the slave address set in the I2C (IC_SAR register) OR if the transfer is completed before IC_ENABLE is set to 0 but has not taken effect. NOTE: If the remote I2C master terminates the transfer with a STOP condition before the I2C module has a chance to NACK a transfer, and IC_ENABLE[0] has been set to 0, then this bit will also be set to 1. When read as 0, the I2C module is deemed to have been disabled when there is master activity, or when the I2C bus is idle. NOTE: The CPU can safely read this bit when IC_EN (bit 0) is read as 0. Reset value: 0x0	RO	0x0
0	ic_en	ic_en Status. This bit always reflects the value driven on the output port ic_en. When read as 1, the I2C module is deemed to be in an enabled state. When read as 0, the I2C module is deemed completely inactive. NOTE: The CPU can safely read this bit anytime. When this bit is read as 0, the CPU can safely read SLV_RX_DATA_LOST (bit 2) and SLV_DISABLED_WHILE_BUSY (bit 1). Reset value: 0x0	RO	0x0

ic_sda_setup on page 4257	0x94	32	RW	0x64	<p>Name: I2C SDA Setup Register Size: 8 bits Address Offset: 0x94 Read/Write Access: Read/Write This register controls the amount of time delay (in terms of number of ic_clk clock periods) introduced in the rising edge of SCL, relative to SDA changing, when DW_apb_i2c services a read request in a slave-transmitter operation. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification.</p>
ic_ack_general_call on page 4258	0x98	32	RW	0x1	<p>Name: I2C ACK General Call Register Size: 1 bit Address Offset: 0x98 Read/Write Access: Read/Write The register controls whether DW_apb_i2c responds with a ACK or NACK when it receives an I2C General Call address. Note :This register is applicable only when the DW_apb_i2c is in slave mode</p>
ic_enable_status on page 4259	0x9C	32	RO	0x0	<p>Name: I2C Enable Status Register Size: 3 bits Address Offset: 0x9C Read/Write Access: Read The register is used to report the DW_apb_i2c hardware status when the IC_ENABLE[0] register is set from 1 to 0; that is, when DW_apb_i2c is disabled. If IC_ENABLE[0] has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1. If IC_ENABLE[0] has been set to 0, bits 2:1 is only be valid as soon as bit 0 is read as '0'. Note When IC_ENABLE[0] has been written with '0'a delay occurs for bit 0 to be read as '0' because disabling the DW_apb_i2c depends on I2C bus activities.</p>
ic_comp_param_1 on page 4261	0xF4	32	RO	0x3F3FEA	<p>Name: Component Parameter Register 1 Size: 32 bits Address Offset: 0xf4 Read/Write Access: Read Note This is a constant read-only register that contains encoded information about the component's parameter settings. The reset value depends on coreConsultant parameter(s).</p>
ic_comp_version on page 4263	0xF8	32	RO	0x3132312A	<p>Name: I2C Component Version Register Size: 32 bits Address Offset: 0xf8 Read/Write Access: Read</p>

Register	Offset	Width	Access	Reset Value	Description
<code>ic_comp_type</code> on page 4263	0xFC	32	RO	0x44570140	Name: I2C Component Type Register Size: 32 bits Address Offset: 0xfc Read/Write Access: Read
<code>ic_fs_spklen</code> on page 4264	0xA0	32	RW	0x2	Name: I2C SS, FS or FM+ spike suppression limit Size: 8 bits Address: 0xA0 Read/Write Access: Read/Write This register is used to store the duration, measured in <code>ic_clk</code> cycles, of the longest spike that is filtered out by the spike suppression logic when the component is operating in SS, FS or FM+ modes. The relevant I2C requirement is tSP (table 4) as detailed in the I2C Bus Specification. This register must be programmed with a minimum value of 1.
<code>ic_clr_restart_det</code> on page 4265	0xA8	32	RO	0x0	Name: Clear RESTART_DET Interrupt Register Size: 1 bit Address Offset: 0xA8 Read/Write Access: Read

21.6.2.3. ic_tar

Name: I2C Target Address Register

All bits can be dynamically updated as long as any set of the following conditions are true:

- The I2C is NOT enabled (IC_ENABLE[0] is set to 0);
or
- The I2C is enabled (IC_ENABLE[0]=1);
AND

```
The I2C is NOT engaged in any Master (tx, rx) operation (IC_STATUS[5]=0);
AND
The I2C is enabled to operate in Master mode (IC_CON[0]=1);
AND
there are NO entries in the TX FIFO (IC_STATUS[2]=1)
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						ic_sar RW 0x55									

ic_sar Fields

Bit	Name	Description	Access	Reset
9:0	ic_sar	<p>The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE[0] register being set to 0. Writes at other times have no effect.</p> <p>Note: The default values cannot be any of the reserved address locations: that is, 0x00 to 0x07, or 0x78 to 0x7f. The correct operation of the device is not guaranteed if you program the IC_SAR or IC_TAR to a reserved value. Reset value: 0x55</p>	RW	0x55

21.6.2.5. ic_data_cmd

I2C Rx/Tx Data Buffer and Command Register;
this is the register the CPU writes to when
filling the TX FIFO and the CPU reads from when
retrieving bytes from RX FIFO
Size:
11 bits (writes), 8 bits (read)

Module Instance	Base Address	Register Address
i_i2c_emac_0_i2c	0xFFC02400	0xFFC02410
i_i2c_emac_1_i2c	0xFFC02500	0xFFC02510
i_i2c_emac_2_i2c	0xFFC02600	0xFFC02610

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved					resta rt WO 0x0	stop WO 0x0	cmd WO 0x0	dat RW 0x0							

ic_data_cmd Fields

Bit	Name	Description	Access	Reset
10	restart	<p>This bit controls whether a RESTART is issued before the byte is sent or received.</p> <p>1 - If IC_RESTART_EN is 1, a RESTART is issued before the data is sent/received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead.</p> <p>0 - If IC_RESTART_EN is 1, a RESTART is issued only if the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead.</p> <p>Reset value: 0x0</p>	WO	0x0
9	stop	<p>This bit controls whether a STOP is issued after the byte is sent or received.</p> <p>1 - STOP is issued after this byte, regardless of whether or not the Tx FIFO is empty. If the Tx FIFO is not empty, the master immediately tries to start a new transfer by issuing a START and arbitrating for the bus.</p> <p>0 - STOP is not issued after this byte, regardless of whether or not the Tx FIFO is empty. If the Tx FIFO is not empty, the master continues the current transfer by sending/receiving data bytes according to the value of the CMD bit. If the Tx FIFO is empty, the master holds the SCL line low and stalls the bus until a new command is available in the Tx FIFO.</p> <p>Reset value: 0x0</p>	WO	0x0
8	cmd	<p>This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It controls only the direction when it acts as a master.</p> <p>1 = Read 0 = Write</p> <p>When a command is entered in the TX FIFO, this bit distinguishes the write and read commands. In slave-receiver mode, this bit is a 'don't care' because writes to this register are not required. In slave-transmitter mode, a '0' indicates that CPU data is to be transmitted and as DAT or IC_DATA_CMD[7:0]. When programming this bit, you should remember the following: attempting to perform a read operation after a General Call command has been sent results in a TX_ABRT interrupt (bit 6 of the IC_RAW_INTR_STAT</p>	WO	0x0

continued...

Bit	Name	Description	Access	Reset						
		<p>register), unless bit 11 (SPECIAL) in the IC_TAR register has been cleared. If a '1' is written to this bit after receiving a RD_REQ interrupt, then a TX_ABRT interrupt occurs.</p> <p>NOTE: It is possible that while attempting a master I2C read transfer on the I2C, a RD_REQ interrupt may have occurred simultaneously due to a remote I2C master addressing the I2C module. In this type of scenario, the I2C module ignores the IC_DATA_CMD write, generates a TX_ABRT interrupt, and waits to service the RD_REQ interrupt.</p> <p>Reset value: 0x0</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0x0</td><td>WR</td></tr><tr><td>0x1</td><td>RD</td></tr></tbody></table>	Value	Description	0x0	WR	0x1	RD		
Value	Description									
0x0	WR									
0x1	RD									
7:0	dat	<p>This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the I2C module. However, when you read this register, these bits return the value of data received on the I2C interface.</p> <p>Reset value: 0x0</p>	RW	0x0

ic_intr_stat Fields

Bit	Name	Description	Access	Reset
13	r_master_on_hold	Indicates whether master is holding the bus and TX FIFO is empty. Reset value: 0x0	RO	0x0
12	r_restart_det	Indicates a RESTART condition has occurred on the I2C interface when the I2C module is operating in slave mode and addressed. Reset value: 0x0	RO	0x0
11	r_gen_call	Set only when a General Call address is received and it is acknowledged. It stays set until it is cleared either by disabling the I2C or when the CPU reads bit 0 of the IC_CLR_GEN_CALL register. The I2C	RO	0x0

continued...

Bit	Name	Description	Access	Reset
		stores the received data in the Rx buffer. Reset value: 0x0		
10	r_start_det	Indicates whether a START or RESTART condition has occurred on the I2C interface regardless of whether the I2C module is operating in slave or master mode. Reset value: 0x0	RO	0x0
9	r_stop_det	The behavior of the STOP_DET interrupt status differs based on the STOP_DET_IFADDRESSED selection in the IC_CON register When STOP_DET_IFADDRESSED = 0 : Indicates whether a STOP condition has occurred on the I2C interface regardless of whether the I2C module is operating in slave or master mode. In slave mode, a STOP_DET interrupt is generated irrespective of whether the slave is addressed or not. When STOP_DET_IFADDRESSED = 1 : In Master Mode (MASTER_MODE = 1'b1), indicates a STOP condition has occurred on the I2C interface. In Slave Mode (MASTER_MODE = 1'b0), STOP_DET interrupt is generated only if the slave is addressed. NOTE: During a general call address, this slave does not issue a STOP_DET interrupt if STOP_DET_IFADDRESSED=1'b1, even if the slave responds to the general call address by generating ACK. The STOP_DET interrupt is generated only when the transmitted address matches the slave address (SAR). Reset value: 0x0	RO	0x0
8	r_activity	This bit captures the I2C module activity and stays set until it is cleared. There are four ways to clear it: - Disabling the I2C module - Reading the IC_CLR_ACTIVITY register - Reading the IC_CLR_INTR register - System reset Once this bit is set, it stays set unless one of the four methods is used to clear it. Even if the I2C module is idle, this bit remains set until cleared, indicating that there was activity on the bus. Reset value: 0x0	RO	0x0
7	r_rx_done	When the I2C module is acting as a slave-transmitter, this bit is set to 1 if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done. Reset value: 0x0	RO	0x0
6	r_tx_abrt	This bit indicates if the I2C module, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'. When this bit is set to 1, the IC_TX_ABRT_SOURCE register indicates the reason why the transmit abort takes places. NOTE: The I2C module flushes/resets/empties the TX FIFO whenever this bit is set. The TX FIFO remains in this flushed state until the register IC_CLR_TX_ABRT is read. Once this read is performed, the	RO	0x0
continued...				

Bit	Name	Description	Access	Reset
		TX FIFO is then ready to accept more data bytes from the APB interface. Reset value: 0x0		
5	r_rd_req	This bit is set to 1 when the I2C module is acting as a slave and another I2C master is attempting to read data from the I2C module. The HPS I2C holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the IC_DATA_CMD register. This bit is set to 0 just after the processor reads the IC_CLR_RD_REQ register. Reset value: 0x0	RO	0x0
4	r_tx_empty	The behavior of the TX_EMPTY interrupt status differs based on the TX_EMPTY_CTRL selection in the IC_CON register. When TX_EMPTY_CTRL = 0: This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register. When TX_EMPTY_CTRL = 1: This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register and the transmission of the address/data from the internal shift register for the most recently popped command is completed. It is automatically cleared by hardware when the buffer level goes above the threshold. When IC_ENABLE[0] is set to 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer any activity, then with ic_en=0, this bit is set to 0. Reset value: 0x0	RO	0x0
3	r_tx_over	Set during transmit if the transmit buffer is filled to the maximum buffer depth (64) and the processor attempts to issue another I2C command by writing to the IC_DATA_CMD register. When the module is disabled, this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0
2	r_rx_full	Set when the receive buffer reaches or goes above the RX_TL threshold in the IC_RX_TL register. It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled (IC_ENABLE[0]=0), the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the IC_ENABLE bit 0 is programmed with a 0, regardless of the activity that continues. Reset value: 0x0	RO	0x0
1	r_rx_over	Set if the receive buffer is completely filled to its maximum receive buffer depth (64) and an additional byte is received from an external I2C device. The I2C module	RO	0x0
continued...				

Bit	Name	Description	Access	Reset
		acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0		
0	r_rx_under	Set if the processor attempts to read the receive buffer when it is empty by reading from the IC_DATA_CMD register. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0

21.6.2.11. ic_intr_mask

I2C Interrupt Mask Register

These bits mask their corresponding interrupt status bits. They are active high; a value of 0 prevents a bit from generating an interrupt.

Module Instance	Base Address	Register Address

ic_raw_intr_stat Fields

Bit	Name	Description	Access	Reset
13	master_on_hold	Indicates whether master is holding the bus and TX FIFO is empty. Reset value: 0x0	RO	0x0
12	restart_det	Indicates whether a RESTART condition has occurred on the I2C interface when the I2C module is operating in Slave mode and the slave is being addressed. (Note: Following are exceptions where the Restart interrupt will not get generated. In the case of Startbyte transfer, where the Restart comes before the Address field as per the I2C protocol defined format, the Slave is still not in the addressed mode and hence will not generate the RESTART_DET interrupt.) Reset value: 0x0	RO	0x0
11	gen_call	Set only when a General Call address is received and it is acknowledged. It stays set until it is cleared either by disabling the I2C module or when the CPU reads bit 0 of the IC_CLR_GEN_CALL register. The I2C stores the received data in the Rx buffer. Reset value: 0x0	RO	0x0
10	start_det	Indicates whether a START or RESTART condition has occurred on the I2C interface regardless of whether the I2C is operating in slave or master mode. Reset value: 0x0	RO	0x0
9	stop_det	The behavior of the STOP_DET interrupt status differs based on the STOP_DET_IFADDRESSED selection in the IC_CON register When STOP_DET_IFADDRESSED = 0 Indicates whether a STOP condition has occurred on the I2C interface regardless of whether DW_apb_i2c is operating in slave or master mode. In slave mode, a STOP_DET interrupt is generated irrespective of whether the slave is addressed or not. When STOP_DET_IFADDRESSED = 1 In Master Mode (MASTER_MODE = 1), indicates a STOP condition has occurred on the I2C interface. In Slave Mode (MASTER_MODE = 0), a STOP_DET interrupt is generated only if the slave is addressed. NOTE: During a general call address, this slave does not issue a STOP_DET interrupt if STOP_DET_IFADDRESSED=1, even if the slave responds to the general call address by generating ACK. The STOP_DET interrupt is generated only when the transmitted address matches the slave address (SAR). Reset value: 0x0.	RO	0x0
8	activity	This bit captures the I2C module activity and stays set until it is cleared. There are four ways to clear it: - Disabling the I2C module - Reading the IC_CLR_ACTIVITY register - Reading the IC_CLR_INTR register - System reset Once this bit is set, it stays set unless one of the four	RO	0x0

continued...

Bit	Name	Description	Access	Reset
		methods is used to clear it. Even if the I2C module is idle, this bit remains set until cleared, indicating that there was activity on the bus. Reset value: 0x0		
7	rx_done	When the I2C module is acting as a slave-transmitter, this bit is set to 1 if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done. Reset value: 0x0	RO	0x0
6	tx_abrt	This bit indicates if the I2C module, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'. When this bit is set to 1, the IC_TX_ABRT_SOURCE register indicates the reason why the transmit abort takes places. NOTE: The I2C module flushes/resets/empties the TX FIFO whenever this bit is set. The TX FIFO remains in this flushed state until the register IC_CLR_TX_ABRT is read. Once this read is performed, the TX FIFO is then ready to accept more data bytes from the APB interface. Reset value: 0x0	RO	0x0
5	rd_req	This bit is set to 1 when the I2C module is acting as a slave and another I2C master is attempting to read data from the I2C module. The I2C module holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the IC_DATA_CMD register. This bit is set to 0 just after the processor reads the IC_CLR_RD_REQ register. Reset value: 0x0	RO	0x0
4	tx_empty	The behavior of the TX_EMPTY interrupt status differs based on the TX_EMPTY_CTRL selection in the IC_CON register. When TX_EMPTY_CTRL = 0: This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register. When TX_EMPTY_CTRL = 1: This bit is set to 1 when the transmit buffer is at or below the threshold value. set in the IC_TX_TL register and the transmission of the address/data from the internal shift register for the most recently popped command is completed. It is automatically cleared by hardware when the buffer level goes above the threshold. When IC_ENABLE[0] is set to 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer any activity, then with ic_en=0, this bit is set to 0. Reset value: 0x0.	RO	0x0
continued...				

Bit	Name	Description	Access	Reset
3	tx_over	Set during transmit if the transmit buffer is filled to the maximum TxFIFO buffer depth (64) and the processor attempts to issue another I2C command by writing to the IC_DATA_CMD register. When the module is disabled, this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0
2	rx_full	Set when the receive buffer reaches or goes above the RX_TL threshold in the IC_RX_TL register. It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled (IC_ENABLE[0]=0), the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the IC_ENABLE bit 0 is programmed with a 0, regardless of the activity that continues. Reset value: 0x0	RO	0x0
1	rx_over	Set if the receive buffer is completely filled to the maximum Rx FIFO buffer depth (64) and an additional byte is received from an external I2C device. The I2C module acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0
0	rx_under	Set if the processor attempts to read the receive buffer when it is empty by reading from the IC_DATA_CMD register. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0

21.6.2.27. ic_status

I2C Status Register

This is a read-only register used to indicate the current transfer status and FIFO status. The status register may be read at any time. None of the bits in this register request an interrupt.

When the I2C is disabled by writing 0 in bit 0 of the IC_ENABLE register:

- Bits 1 and 2 are set to 1
- Bits 3 and 4 are set to 0

When the master or slave state machines goes to idle and ic_en=0:

- Bits 5 and 6 are set to 0

Module Instance	Base Address	Register Address

21.6.2.28. ic_txflr

Name: I2C Transmit FIFO Level Register

This register contains the number of valid data entries in the transmit FIFO buffer. It is cleared whenever:

- The I2C is disabled
- There is a transmit abort that is, TX_ABRT bit is set in the IC_RAW_INTR_STAT register
- The slave bulk transmit mode is aborted

The register increments whenever data is placed into the transmit FIFO and decrements when data is taken from the transmit FIFO.

Module Instance	Base Address	Register Address

6:0	rxflr	Receive FIFO Level. Contains the number of valid data entries in the receive FIFO. Reset value: 0x0	RO	0x0

21.6.2.30. ic_sda_hold

I2C SDA Hold Time Length Register

The bits [15:0] of this register are used to control the hold time of SDA during transmit in both slave and master mode (after SCL goes from HIGH to LOW). The bits [23:16] of this register are used to extend the SDA transition (if any) whenever SCL is HIGH in the receiver in either master or slave mode. The values in this register are in units of l4_sp_clk period. This register controls the amount of time delay. The relevant I2C requirement is thd:DAT as detailed in the I2C Bus Specification.

Module Instance	Base Address	Register Address
i_i2c_emac_0_i2c	0xFFC02400	0xFFC0247C
i_i2c_emac_1_i2c	0xFFC02500	0xFFC0257C
i_i2c_emac_2_i2c	0xFFC02600	0xFFC0267C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15:0	ic_sda_tx_hold	Sets the required SDA hold time in units of l4_sp_clk period, when the I2C module acts as a transmitter.	RW	0x1

21.6.2.31. ic_tx_abrt_source

I2C Transmit Abort Source Register

This register has 32 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

Module Instance	Base Address	Register Address
i_i2c_emac_0_i2c	0xFFC02400	0xFFC02480
i_i2c_emac_1_i2c	0xFFC02500	0xFFC02580
i_i2c_emac_2_i2c	0xFFC02600	0xFFC02680

Offset: 0x80

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

ic_tx_abrt_source Fields

Bit	Name	Description	Access	Reset
31:2 3	tx_flush_cnt	This field indicates the number of Tx FIFO Data Commands which are flushed due to TX_ABORT interrupt. It is cleared whenever I2C is disabled. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Slave-Transmitter	RO	0x0
22:1 7	rsvd_ic_tx_abrt_source_22to17	Reserved Reset value: 0x0	RO	0x0
16	abrt_user_abrt	This is a master-mode-only bit. Master has detected the transfer abort (IC_ENABLE[1]) Reset value: 0x0 Role of the I2C module: Master-Transmitter	RO	0x0
15	abrt_slvrd_intx	1: When the processor side responds to a slave mode request for data to be transmitted to a remote master and user writes a 1 in CMD (bit 8) of IC_DATA_CMD register. Reset value: 0x0 Role of the I2C module: Slave-Transmitter	RO	0x0
14	abrt_slv_arblost	1: Slave lost the bus while transmitting data to a remote master. IC_TX_ABORT_SOURCE[12] is set at the same time. Note: Even though the slave never 'owns' the bus, something could go wrong on the bus. This is a fail safe check. For instance, during a data transmission at the low-to-high transition of SCL, if what is on the data bus is not what is supposed to be transmitted, then the I2C module no longer owns the bus. Reset value: 0x0 Role of the I2C module: Slave-Transmitter	RO	0x0
13	abrt_slvflush_txfifo	1: Slave has received a read command and some data exists in the TX FIFO so the slave issues a TX_ABORT interrupt to	RO	0x0

continued...

Bit	Name	Description	Access	Reset
		flush old data in TX FIFO. Reset value: 0x0 Role of the I2C module: Slave-Transmitter		
12	arb_lost	1: Master has lost arbitration, or if IC_TX_ABRT_SOURCE[14] is also set, then the slave transmitter has lost arbitration. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Slave-Transmitter	RO	0x0
11	abrt_master_dis	1: User tries to initiate a Master operation with the Master mode disabled. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0
10	abrt_10b_rd_norstrt	1: The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) = 0) and the master sends a read command in 10-bit addressing mode. Reset value: 0x0 Role of the I2C module: Master-Receiver	RO	0x0
9	abrt_sbyte_norstrt	To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; restart must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, bit 9 clears for one cycle and then gets reasserted. 1: The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) = 0) and the user is trying to send a START Byte. Reset value: 0x0 Role of the I2C module: Master	RO	0x0
8	abrt_hs_norstrt	1: The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) = 0) and the user is trying to use the master to transfer data in High Speed mode. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0
7	abrt_sbyte_ackdet	1: Master has sent a START Byte and the START Byte was acknowledged (wrong behavior). Reset value: 0x0 Role of the I2C module: Master	RO	0x0
6	abrt_hs_ackdet	1: Master is in High Speed mode and the High Speed Master code was acknowledged (wrong behavior). Reset value: 0x0 Role of the I2C module: Master	RO	0x0
continued...				

Bit	Name	Description	Access	Reset
5	abrt_gcall_read	1: The I2C module in master mode sent a General Call but the user programmed the byte following the General Call to be a read from the bus (IC_DATA_CMD[9] is set to 1). Reset value: 0x0 Role of the I2C module: Master-Transmitter	RO	0x0
4	abrt_gcall_noack	1: The I2C module in master mode sent a General Call and no slave on the bus acknowledged the General Call. Reset value: 0x0 Role of the I2C module: Master-Transmitter	RO	0x0
3	abrt_txdata_noack	1: This is a master-mode only bit. Master has received an acknowledgement for the address, but when it sent data byte(s) following the address, it did not receive an acknowledge from the remote slave(s). Reset value: 0x0 Role of the I2C module: Master-Transmitter	RO	0x0
2	abrt_10addr2_noack	1: Master is in 10-bit address mode and the second address byte of the 10-bit address was not acknowledged by any slave. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0
1	abrt_10addr1_noack	1: Master is in 10-bit address mode and the first 10-bit address byte was not acknowledged by any slave. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0
0	abrt_7b_addr_noack	1: Master is in 7-bit addressing mode and the address sent was not acknowledged by any slave. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0

21.6.2.32. ic_slv_data_nack_only

Generate Slave Data NACK Register

The register is used to generate a NACK for the data part of a transfer when the I2C module is acting as a slave-receiver.

Module Instance	Base Address	Register Address
i_i2c_emac_0_i2c	0xFFC02400	0xFFC02484
i_i2c_emac_1_i2c	0xFFC02500	0xFFC02584

Value	Description									
0x0	NACK									
0x1	ACK									

21.6.2.38. ic_enable_status

I2C Enable Status Register

The register is used to report the I2C hardware status when the IC_ENABLE[0] register is set from 1 to 0; that is, when the I2C module is disabled.
If IC_ENABLE[0] has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1.
If IC_ENABLE[0] has been set to 0, bits 2:1 is only be valid as soon as bit 0 is read as '0'.
Note
When IC_ENABLE[0] has been written with '0'a delay occurs for bit 0 to be read as '0' because disabling the I2C module depends on I2C bus activities.

Module Instance	Base Address	Register Address
i_i2c_emac_0_i2c	0xFFC02400	0xFFC0249C
i_i2c_emac_1_i2c	0xFFC02500	0xFFC0259C

22. UART Controller

The hard processor system (HPS) provides two UART controllers for asynchronous serial communication. The UART controllers are based on an industry standard 16550 UART controller. The UART controllers are instances of the Synopsys DesignWare APB Universal Asynchronous Receiver/Transmitter (DW_apb_uart) peripheral. ⁽⁵⁶⁾

22.1. UART Controller Features

The UART controller provides the following functionality and features:

- Programmable character properties, such as number of data bits per character, optional parity bits, and number of stop bits †
- Line break generation and detection †
- DMA controller handshaking interface
- Prioritized interrupt identification †
- Programmable baud rate
- False start bit detection †
- Automatic flow control mode per 16750 standard †
- Internal loopback mode support
- 128-byte transmit and receive FIFO buffers
 - FIFO buffer status registers †
 - FIFO buffer access mode (for FIFO buffer testing) enables write of receive FIFO buffer by master and read of transmit FIFO buffer by master †

22.2. UART Controller Block Diagram and System Integration

Figure 174. UART Block Diagram

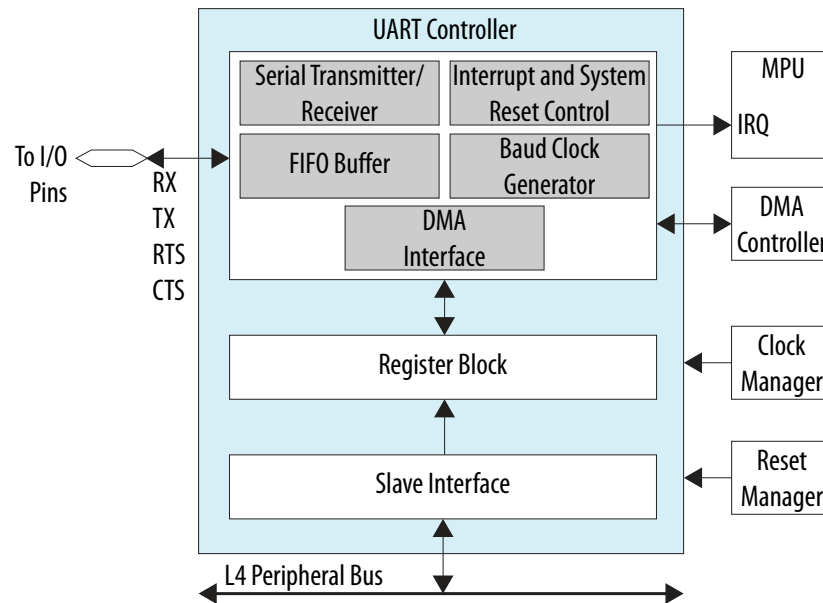

Table 249. UART Controller Block Descriptions

Block	Description
Slave interface	Slave interface between the component and L4 peripheral bus.
Register block	Provides main UART control, status, and interrupt generation functions.†
FIFO buffer	Provides FIFO buffer control and storage. †
Baud clock generator	Generates the transmitter and receiver baud clock. With a reference clock of 100 MHz, the UART controller supports transfer rates of 95 baud to 6.25 Mbaud. This supports communication with all known 16550 devices. The baud rate is controlled by programming the interrupt enable or divisor latch high (IER_DLH) and receive buffer, transmit holding, or divisor latch low (RBR_THR_DLL) registers.
Serial transmitter	Converts parallel data written to the UART into serial data and adds all additional bits, as specified by the control register, for transmission. This makeup of serial data, referred to as a character, exits the block in serial UART. †
Serial receiver	Converts the serial data character (as specified by the control register) received in the UART format to parallel form. Parity error detection, framing error detection and line break detection is carried out in this block. †
DMA interface	The UART controller includes a DMA controller interface to indicate when received data is available or when the transmit FIFO buffer requires data. The DMA requires two channels, one for transmit and one for receive. The UART controller supports single and burst transfers. You can use DMA in FIFO buffer and non-FIFO buffer mode.

22.4. Functional Description of the UART Controller

The HPS UART is based on an industry-standard 16550 UART. The UART supports serial communication with a peripheral, modem (data carrier equipment), or data set. The master (CPU) writes data over the slave bus to the UART. The UART converts the data to serial format and transmits to the destination device. The UART also receives serial data and stores it for the master (CPU). †

The UART's registers control the character length, baud rate, parity generation and checking, and interrupt generation. The UART's single interrupt output signal is supported by several prioritized interrupt types that trigger assertion. You can separately enable or disable each of the interrupt types with the control registers. †

22.4.1. FIFO Buffer Support

The UART controller includes 128-byte FIFO buffers to buffer transmit and receive data. FIFO buffer access mode allows the master to write the receive FIFO buffer and to read the transmit FIFO buffer for test purposes. FIFO buffer access mode is enabled with the FIFO access register (FAR). Once enabled, the control portions of the transmit and receive FIFO buffers are reset and the FIFO buffers are treated as empty. †

When FIFO buffer access mode is enabled, you can write data to the transmit FIFO buffer as normal; however, no serial transmission occurs in this mode and no data leaves the FIFO buffer. You can read back the data that is written to the transmit FIFO buffer with the transmit FIFO read (TFR) register. The TFR register provides the current data at the top of the transmit FIFO buffer. †

Similarly, you can also read data from the receive FIFO buffer in FIFO buffer access mode. Since the normal operation of the UART is halted in this mode, you must write data to the receive FIFO buffer to read it back. The receive FIFO write (RFW) register writes data to the receive FIFO buffer. The upper two bits of the 10-bit register write framing errors and parity error detection information to the receive FIFO buffer. Bit 9 of RFW indicates a framing error and bit 8 of RFW indicates a parity error. Although you cannot read these bits back from the receive buffer register, you can check the bits by reading the line status register (LSR), and by checking the corresponding bits when the data in question is at the top of the receive FIFO buffer. †

22.4.2. UART(RS232) Serial Protocol

Because the serial communication between the UART controller and the selected device is asynchronous, additional bits (start and stop) are added to the serial data to indicate the beginning and end. Utilizing these bits allows two devices to be synchronized. This structure of serial data accompanied by start and stop bits is referred to as a character, as shown in below.†

Figure 175. Serial Data Format

An additional parity bit may be added to the serial character. This bit appears after the last data bit and before the stop bit(s) in the character structure to provide the UART controller with the ability to perform simple error checking on the received data.†

The Control Register is used to control the serial character characteristics. The individual bits of the data word are sent after the start bit, starting with the least-significant bit (LSB). These are followed by the optional parity bit, followed by the stop bit(s), which can be 1, 1.5 or 2.†

All the bits in the transmission (with exception to the half stop bit when 1.5 stop bits are used) are transmitted for exactly the same time duration. This is referred to as a Bit Period or Bit Time. One Bit Time equals 16 baud clocks. To ensure stability on the line, the receiver samples the serial input data at approximately the midpoint of the Bit Time once the start bit has been detected. Because the exact number of baud clocks that each bit transmission is known, calculating the midpoint for sampling is not difficult. That is, every 16 baud clocks after the midpoint sample of the start bit.†

Together with serial input debouncing, this feature also contributes to avoid the detection of false start bits. Short glitches are filtered out by debouncing, and no transition is detected on the line. If a glitch is wide enough to avoid filtering by debouncing, a falling edge is detected. However, a start bit is detected only if the line is sampled low again after half a bit time has elapsed. †

Figure 176. Receiver Serial Data Sample Points

The baud rate of the UART controller is controlled by the serial clock and the Divisor Latch Register (DLH and DLL).†

22.4.3. Automatic Flow Control

The UART includes 16750-compatible request-to-send (RTS) and clear-to-send (CTS) serial data automatic flow control mode. You enable automatic flow control with the modem control register (MCR.AFCE). †

22.4.3.1. RTC Flow Control Trigger

RTC is an RX FIFO Almost-Full Trigger, where "almost full" refer to two available slots in the FIFO.

The UART controller uses two separate trigger levels for a DMA request and handshake signal (rts_n) in order to maximize throughput on the interface.

22.4.3.2. Automatic RTS mode

Automatic RTS mode becomes active when the following conditions occur: †

- RTS (MCR.RTS bit and MCR.AFCE bit are both set)
- FIFO buffers are enabled (FCR.FIFOE bit is set)

With automatic RTS enabled, the `rts_n` output pin is forced inactive (high) when the FIFO is almost full; where "almost full" refers to two available slots in the FIFO. When `rts_n` is connected to the `cts_n` input pin of another UART device, the other UART stops sending serial data until the receive FIFO buffer has available space (until it is completely empty). †

The selectable receive FIFO buffer threshold values are 1, $\frac{1}{4}$, $\frac{1}{2}$, and 2 less than full. Because one additional character may be transmitted to the UART after `rts_n` is inactive (due to data already having entered the transmitter block in the other UART), setting the threshold to 2 less than full allows maximum use of the FIFO buffer with a margin of one character. †

Once the receive FIFO buffer is completely emptied by reading the receiver buffer register (RBR_THR_DLL), `rts_n` again becomes active (low), signaling the other UART to continue sending data. †

Even when you set the correct MCR bits, if the FIFO buffers are disabled through FCR.FIFOE, automatic flow control is also disabled. When auto RTS is not implemented or disabled, `rts_n` is controlled solely by MCR.RTS. In the Automatic RTS Timing diagram, the character T is received because `rts_n` is not detected prior to the next character entering the sending UART transmitter. †

Figure 177. Automatic RTS Timing

22.4.3.3. Automatic CTS mode

Automatic CTS mode becomes active when the following conditions occur: †

- AFCE (MCR.AFCE bit is set)
- FIFO buffers are enabled (through FIFO buffer control register IIR_FCR.FIFOE) bit

When automatic CTS is enabled (active), the UART transmitter is disabled whenever the `cts_n` input becomes inactive (high). This prevents overflowing the FIFO buffer of the receiving UART. †

If the `cts_n` input is not deactivated before the middle of the last stop bit, another character is transmitted before the transmitter is disabled. While the transmitter is disabled, you can continue to write and even overflow to the transmit FIFO buffer. †

Automatic CTS mode requires the following sequence:

1. The UART status register are read to verify that the transmit FIFO buffer is full (UART status register `USR.TFNF` set to zero). †
2. The current FIFO buffer level is read via the transmit FIFO level (`TFL`) register. †
3. Programmable THRE interrupt mode must be enabled to access the FIFO buffer full status from the LSR. †

When using the FIFO buffer full status, software can poll this before each write to the transmit FIFO buffer. When the `cts_n` input becomes active (low) again, transmission resumes. If the FIFO buffers are disabled with the `FCR.FIFOE` bit, automatic flow control is also disabled regardless of any other settings. When auto CTS is not implemented or disabled, the transmitter is unaffected by `cts_n`.†

Figure 178. Automatic CTS Timing

22.4.4. Clocks

The UART controller is connected to the `l4_sp_clk` clock. The clock input is driven by the clock manager.

Related Information

[Clock Manager](#) on page 56

For more information, refer to the *Clock Manager* chapter.

22.4.5. Resets

The UART controller is connected to the `uart_rst_n` reset signal. The reset manager drives the signal on a cold or warm reset.

22.4.5.1. Taking the UART Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Related Information

[Reset Manager](#) on page 138

For more information, refer to the *Reset Manager* chapter.

22.4.6. Interrupts

The assertion of the UART interrupt output signal occurs when one of the following interrupt types are enabled and active: †

Table 252. Interrupt Types and Priority †

Interrupt Type	Priority	Source	Interrupt Reset Control
Receiver line status	Highest	Overrun, parity and framing errors, break condition.	Reading the line status Register.
Received data available	Second	Receiver data available (FIFOs disabled) or RCVR FIFO trigger level reached (FIFOs enabled).	Reading the receiver buffer register (FIFOs disabled) or the FIFO drops below the trigger level (FIFOs enabled)
Character timeout indication	Second	No characters in or out of the Receive FIFO during the last 4 character times and there is at least 1 character in it during this Time.	Reading the receiver buffer Register.
Transmit holding register empty	Third	Transmitter holding register empty (Programmable THRE Mode disabled) or Transmit FIFO at or below threshold (Programmable THRE Mode enabled).	Reading the IIR register (if source of interrupt); or, writing into THR (FIFOs or Programmable THRE Mode not enabled) or Transmit FIFO above threshold (FIFOs and Programmable THRE Mode enabled).
Modem Status	Fourth	Clear to send or data set ready or ring indicator or data carrier detect. If auto flow control mode is enabled, a change in CTS (that is, DCTS set) does not cause an interrupt.	Reading the Modem status Register.

You can enable the interrupt types with the interrupt enable register (IER_DLH).

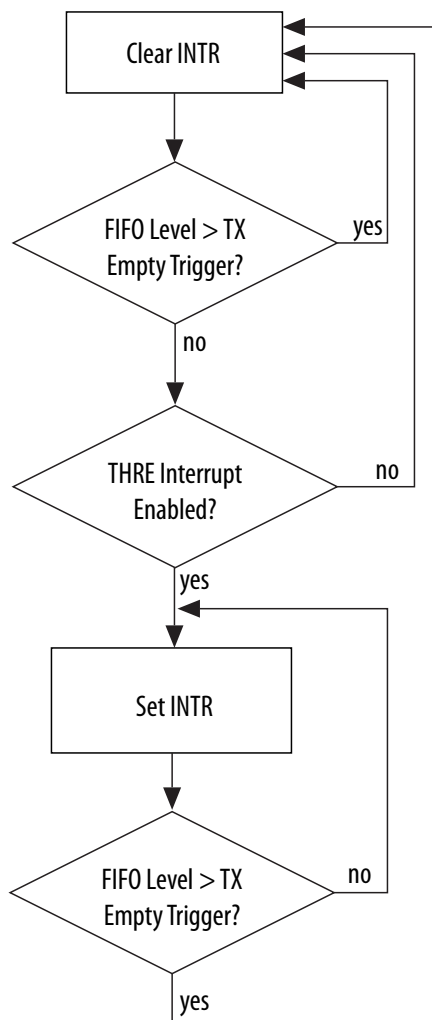

Note: Received Data Available" and "Character Timeout Indication" are enabled by a single bit in the IER_DLH register, because they have the same priority.

Once an interrupt is signaled, you can determine the interrupt source by reading the Interrupt Identity Register (IIR).

22.4.6.1. Programmable THRE Interrupt

The UART has a programmable THRE interrupt mode to increase system performance. You enable the programmable THRE interrupt mode with the interrupt enable register (IER_DLH.PTIME). When the THRE mode is enabled, THRE interrupts and the dma_tx_req signal are active at and below a programmed transmit FIFO buffer empty threshold level, as shown in the flowchart. †

Figure 179. Programmable THRE Interrupt

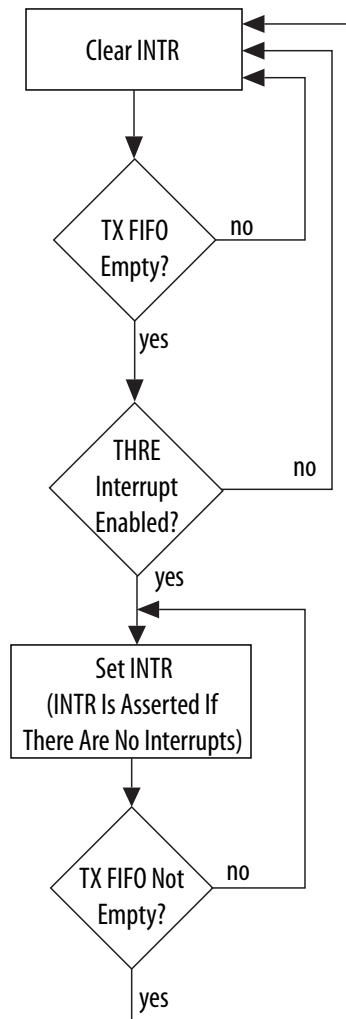

The threshold level is programmed into `FCR.TET`. The available empty thresholds are empty, 2, $\frac{1}{4}$, and $\frac{1}{2}$. The optimum threshold value depends on the system's ability to begin a new transmission sequence in a timely manner. However, one of these thresholds should prove optimum in increasing system performance by preventing the transmit FIFO buffer from running empty.

In addition to the interrupt change, line status register (`LSR.THRE`) also switches from indicating that the transmit FIFO buffer is empty, to indicating that the FIFO buffer is full. This change allows software to fill the FIFO buffer for each transmit sequence by polling `LSR.THRE` before writing another character. This directs the UART to fill the transmit FIFO buffer whenever an interrupt occurs and there is data to transmit, instead of waiting until the FIFO buffer is completely empty. Waiting until the FIFO buffer is empty reduces performance whenever the system is too busy to respond immediately. You can increase system efficiency when this mode is enabled in combination with automatic flow control.

When not selected or disabled, THRE interrupts and `LSR.THRE` function normally, reflecting an empty THR or FIFO buffer.

Figure 180. Interrupt Generation without Programmable THRE Interrupt Mode

22.5. DMA Controller Operation

The UART controller includes a DMA controller interface to indicate when the receive FIFO buffer data is available or when the transmit FIFO buffer requires data. The DMA requires two channels, one for transmit and one for receive. The UART controller supports both single and burst transfers.

The FIFO buffer depth (`FIFO_DEPTH`) for both the RX and TX buffers in the UART controller is 128 entries.

Related Information

[DMA Controller](#) on page 1969

For more information, refer to the DMA Controller chapter.

22.5.1. Transmit FIFO Underflow

During UART serial transfers, transmit FIFO requests are made to the DMA controller whenever the number of entries in the transmit FIFO is less than or equal to the decoded level of the Transmit Empty Trigger (TET) field in the FIFO Control Register (FCR), also known as the watermark level. The DMA controller responds by writing a burst of data to the transmit FIFO buffer, of length specified as DMA burst length. †

Data should be fetched from the DMA often enough for the transmit FIFO to perform serial transfers continuously, that is, when the FIFO begins to empty, another DMA request should be triggered. Otherwise, the FIFO will run out of data (underflow) causing a STOP to be inserted on the UART bus. To prevent this condition, you must set the watermark level correctly. †

Related Information

[DMA Controller](#) on page 1969

For more information, refer to the DMA Controller chapter.

22.5.2. Transmit Watermark Level

Consider the example where the following assumption is made: †

DMA burst length = $FIFO_DEPTH - \text{decoded watermark level of } IIR_FCR.TET$ †

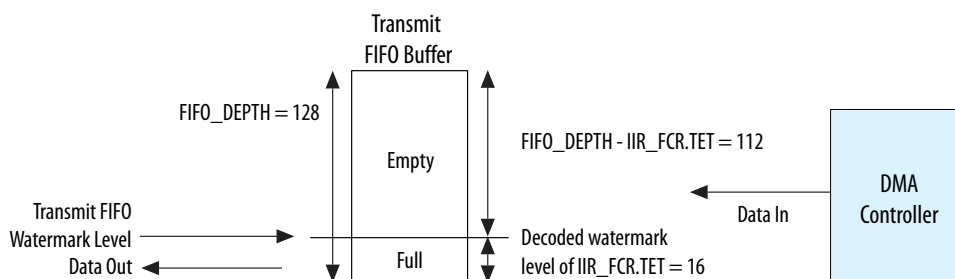

Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO. Consider the following two different watermark level settings: †

22.5.2.1. $IIR_FCR.TET = 1$

$IIR_FCR.TET = 1$ decodes to a watermark level of 16.

- Transmit FIFO watermark level = decoded watermark level of $IIR_FCR.TET = 16$ †
- DMA burst length = $FIFO_DEPTH - \text{decoded watermark level of } IIR_FCR.TET = 112$ †
- UART transmit $FIFO_DEPTH = 128$ †
- Block transaction size = 448†

Figure 181. Transmit FIFO Watermark Level = 16

The number of burst transactions needed equals the block size divided by the number of data items per burst:

$$\text{Block transaction size/DMA burst length} = 448/112 = 4$$

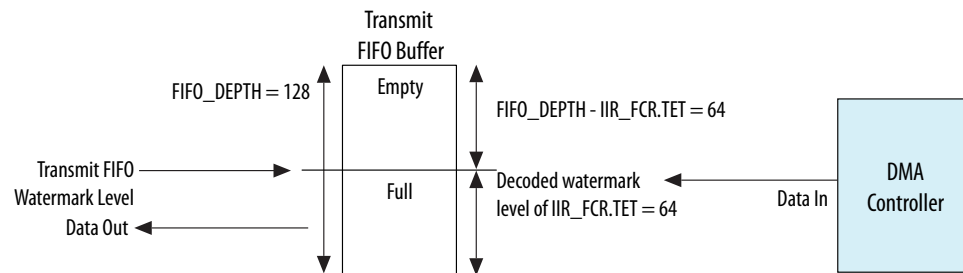

The number of burst transactions in the DMA block transfer is 4. But the watermark level, decoded level of `IIR_FCR.TET`, is quite low. Therefore, the probability of transmit underflow is high where the UART serial transmit line needs to transmit data, but there is no data left in the transmit FIFO. This occurs because the DMA has not had time to service the DMA request before the FIFO becomes empty.

22.5.2.2. IIR_FCR.TET = 3

`IIR_FCR.TET` = 3 decodes to a watermark level of 64.

- Transmit FIFO watermark level = decoded watermark level of `IIR_FCR.TET` = 64 †
- DMA burst length = `FIFO_DEPTH` - decoded watermark level of `IIR_FCR.TET` = 64 †
- UART transmit `FIFO_DEPTH` = 128 †
- Block transaction size = 448 †

Figure 182. Transmit FIFO Watermark Level = 64

Number of burst transactions in block: †

$$\text{Block transaction size/DMA burst length} = 448/64 = 7 \dagger$$

In this block transfer, there are 15 destination burst transactions in a DMA block transfer. But the watermark level, decoded level of `IIR_FCR.TET`, is high. Therefore, the probability of UART transmit underflow is low because the DMA controller has plenty of time to service the destination burst transaction request before the UART transmit FIFO becomes empty. †

Thus, the second case has a lower probability of underflow at the expense of more burst transactions per block. This provides a potentially greater amount of bursts per block and worse bus utilization than the former case. †

Therefore, the goal in choosing a watermark level is to minimize the number of transactions per block, while at the same time keeping the probability of an underflow condition to an acceptable level. In practice, this is a function of the ratio of the rate at which the UART transmits data to the rate at which the DMA can respond to destination burst requests. †

22.5.3. Transmit FIFO Overflow

Setting the DMA burst length to a value greater than the watermark level that triggers the DMA request might cause overflow when there is not enough space in the transmit FIFO to service the destination burst request. Therefore, the following equation must be adhered to in order to avoid overflow: †

$$\text{DMA burst length} \leq \text{FIFO_DEPTH} - \text{decoded watermark level of IIR_FCR.TET}$$

In case 2: decoded watermark level of IIR_FCR.TET = 64, the amount of space in the transmit FIFO at the time of the burst request is made is equal to the DMA burst length. Thus, the transmit FIFO may be full, but not overflowed, at the completion of the burst transaction. †

Therefore, for optimal operation, DMA burst length must be set at the FIFO level that triggers a transmit DMA request; that is: †

$$\text{DMA burst length} = \text{FIFO_DEPTH} - \text{decoded watermark level of IIR_FCR.TET}$$

Adhering to this equation reduces the number of DMA bursts needed for block transfer, and this in turn improves bus utilization. †

The transmit FIFO will not be full at the end of a DMA burst transfer if the UART controller has successfully transmitted one data item or more on the UART serial transmit line during the transfer. †

22.5.4. Receive FIFO Overflow

During UART serial transfers, receive FIFO requests are made to the DMA whenever the number of entries in the receive FIFO is at or above the decoded level of Receive Trigger (RT) field in the FIFO Control Register (IIR_FCR). This is known as the watermark level. The DMA responds by fetching a burst of data from the receive FIFO. †

Data should be fetched by the DMA often enough for the receive FIFO to accept serial transfers continuously, that is, when the FIFO begins to fill, another DMA transfer is requested. Otherwise the FIFO will fill with data (overflow). To prevent this condition, the user must set the watermark level correctly. †

22.5.5. Receive Watermark Level

Similar to choosing the transmit watermark level described earlier, the receive watermark level, decoded watermark level of IIR_FCR.RT, should be set to minimize the probability of overflow, as shown in the Receive FIFO Buffer diagram. It is a tradeoff between the number of DMA burst transactions required per block versus the probability of an overflow occurring. †

22.5.6. Receive FIFO Underflow

Setting the source transaction burst length greater than the watermark level can cause underflow where there is not enough data to service the source burst request. Therefore, the following equation must be adhered to avoid underflow: †

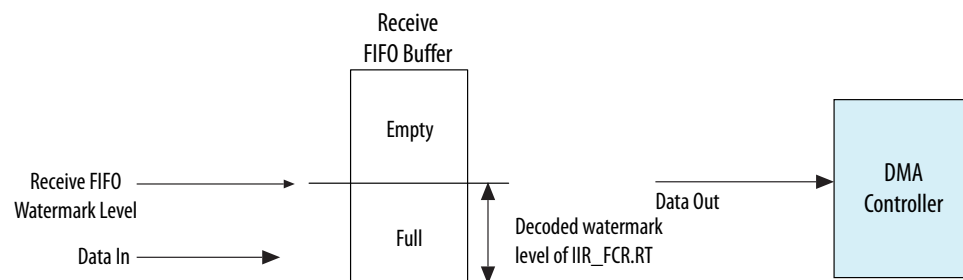

$$\text{DMA burst length} = \text{decoded watermark level of IIR_FCR.RT} + 1$$

If the number of data items in the receive FIFO is equal to the source burst length at the time of the burst request is made, the receive FIFO may be emptied, but not underflowed, at the completion of the burst transaction. For optimal operation, DMA burst length should be set at the watermark level, decoded watermark level of IIR_FCR.RT. †

Adhering to this equation reduces the number of DMA bursts in a block transfer, which in turn can avoid underflow and improve bus utilization. †

The receive FIFO will not be empty at the end of the source burst transaction if the UART controller has successfully received one data item or more on the UART serial receive line during the burst. †

Figure 183. Receive FIFO Buffer

22.6. UART Controller Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the [Arria 10 HPS Address Map and Register Definitions](#).

22.6.1. uart Address Map

Module Instance	Base Address	End Address
i_uart_0_uart	0xFFC02000	0xFFC020FF
i_uart_1_uart	0xFFC02100	0xFFC021FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

msr on page 4312	0x18	32	RO	0x0	Modem Status Register It should be noted that whenever bits 0, 1, 2 or 3 is set to logic one, to indicate a change on the modem control inputs, a modem status interrupt will be generated if enabled via the IER regardless of when the change occurred. Since the delta bits (bits 0, 1, 3) can get set after a reset if their respective modem signals are active (see individual bits for details), a read of the MSR after reset can be performed to prevent unwanted interrupts.

22.6.1.2. rbr_thr_dll

This is a multi-function register. This register holds receives and transmit data and controls the least-significant 8 bits of the baud rate divisor.

Module Instance	Base Address	Register Address
i_uart_0_uart	0xFFC02000	0xFFC02000
i_uart_1_uart	0xFFC02100	0xFFC02100

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

rbr_thr_dll Fields

Bit	Name	Description	Access	Reset
31:8	rsvd_rbr_thr_dll_31to8	Reserved bits [31:8] - Read Only	RO	0x0
7:0	value	<p>Receive Buffer Register: This register contains the data byte received on the serial input port (uart_rxd). The data in this register is valid only if the Data Ready (bit [0] in the Line Status Register(LSR)) is set to 1. If FIFOs are disabled(bit[0] of Register FCR is set to 0) the data in the RBR must be read before the next data arrives, otherwise it will be overwritten, resulting in an overrun error. If FIFOs are enabled(bit [0] of Register FCR is set to 1) this register accesses the head of the receive FIFO. If the receive FIFO is full, and this register is not read before the next data character arrives, then the data already in the FIFO will be preserved but any incoming data will be lost. An overrun error will also occur.</p> <p>Transmit Holding Register: This register contains data to be transmitted on the serial output port. Data should only be written to the THR when the THR Empty bit [5] of the LSR Register is set to 1. If FIFOs are disabled (bit [0] of Register FCR) is set to 0 and THRE is set to 1, writing a single character to the THR clears the THRE. Any additional writes to the THR before the THRE is set again causes the THR data to be overwritten. If FIFO's are enabled bit [0] of Register FCR is set to 1 and THRE is set up to 128 characters of data may be</p>	RW	0x0

continued...

Bit	Name	Description	Access	Reset
		written to the THR before the FIFO is full. Any attempt to write data when the FIFO is full results in the write data being lost. Divisor Latch Low: This register makes up the lower 8-bits of a 16-bit, Read/write, Divisor Latch register that contains the baud rate divisor for the UART. This register may only be accessed when the DLAB bit [7] of the LCR Register is set to 1. The output baud rate is equal to the serial clock l4_sp_clk frequency divided by sixteen times the value of the baud rate divisor, as follows: $\text{baud rate} = (\text{serial clock freq}) / (16 * \text{divisor})$ Note that with the Divisor Latch Registers (DLL and DLH) set to zero, the baud clock is disabled and no serial communications will occur. Also, once the DLL is set, at least 8 l4_sp_clk clock cycles should be allowed to pass before transmitting or receiving data.		

22.6.1.3. ier_dlh

This is a multi-function register. This register enables/disables receive and transmit interrupts and also controls the most-significant 8-bits of the baud rate divisor.

Divisor Latch High Register:
This register is accessed when the DLAB bit [7] of the LCR Register is set to 1. Bits[7:0] contain the high order 8-bits of the baud rate divisor. The output baud rate is equal to the serial clock l4_sp_clk frequency divided by sixteen times the value of the baud rate divisor, as follows:
 $\text{baud rate} = (\text{serial clock freq}) / (16 * \text{divisor})$
Note that with the Divisor Latch Registers (DLL and DLH) set to zero, the baud clock is disabled and no serial communications will occur. Also, once the DLL is set, at least 8 l4_sp_clk clock cycles should be allowed to pass before transmitting or receiving data.

Interrupt Enable Register:
This register may only be accessed when the DLAB bit [7] of the LCR Register is set to 0. Allows control of the Interrupt Enables for transmit and receive functions.

Module Instance	Base Address	Register Address
i_uart_0_uart	0xFFC02000	0xFFC02004
i_uart_1_uart	0xFFC02100	0xFFC02104

Offset: 0x4

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit	Name	Description	Access	Reset						
31:8	rsvd_lsr_31to8	Reserved bits [31:8] - Read Only	RO	0x0						
7	rfe	<p>Receiver FIFO Error bit. This bit is only relevant when FIFO_MODE != NONE AND FIFO's are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. That is: 0 = no error in RX FIFO 1 = error in RX FIFO This bit is cleared when the LSR is read and the character with the error is at the top of the receiver FIFO and there are no subsequent errors in the FIFO.</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0</td><td>NOERR</td></tr><tr><td>1</td><td>ERR</td></tr></table>	Value	Description	0	NOERR	1	ERR	RO	0x0
Value	Description									
0	NOERR									
1	ERR									
6	temt	<p>Transmitter Empty bit. If in FIFO mode (FIFO_MODE != NONE) and FIFO's enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If in the non-FIFO mode or FIFO's are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty.</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0</td><td>NOTEMPTY</td></tr><tr><td>1</td><td>EMPTY</td></tr></table>	Value	Description	0	NOTEMPTY	1	EMPTY	RO	0x1
Value	Description									
0	NOTEMPTY									
1	EMPTY									
5	thre	<p>Transmit Holding Register Empty bit. If THRE_MODE_USER == Disabled or THRE mode is disabled (IER[7] set to zero) and regardless of FIFO's being implemented/enabled or not, this bit indicates that the THR or TX FIFO is empty. This bit is set whenever data</p>	RO	0x1						

continued...

continued...

Bit	Name	Description	Access	Reset						
		<p>is transferred from the THR or TX FIFO to the transmitter shift register and no new data has been written to the THR or TX FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If THRE_MODE_USER == Enabled AND FIFO_MODE != NONE and both modes are active (IER[7] set to one and FCR[0] set to one respectively), the functionality is switched to indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] threshold setting. Programmable THRE interrupt mode operation is described in detail in section 5.7 on page 52.</p>								
4	bi	<p>Break Interrupt bit. This is used to indicate the detection of a break sequence on the serial input data. If in UART mode it is set whenever the serial input, sin, is held in a logic '0' state for longer than the sum of start time + data bits + parity + stop bits. If in infrared mode it is set whenever the serial input, sir_in, is continuously pulsed to logic '0' for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. In the FIFO mode, the character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit. In the non-FIFO mode, the BI indication occurs immediately and persists until the LSR is read.</p>	RO	0x0						
3	fe	<p>Framing Error bit. This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs the UART will try resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit (LSR[3]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). 0 = no framing error 1 = framing error Reading the LSR clears the FE bit.</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0</td><td>NOFRAMEERR</td></tr><tr><td>1</td><td>FRAMEERR</td></tr></table>	Value	Description	0	NOFRAMEERR	1	FRAMEERR	RO	0x0
Value	Description									
0	NOFRAMEERR									
1	FRAMEERR									
2	pe	<p>Parity Error bit. This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. In the FIFO mode,</p>	RO	0x0						

continued...

continued...

Bit	Name	Description	Access	Reset						
		<p>since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]).</p> <p>0 = no parity error 1 = parity error Reading the LSR clears the PE bit.</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0</td><td>NOPARITYERR</td></tr><tr><td>1</td><td>PARITYERR</td></tr></table>	Value	Description	0	NOPARITYERR	1	PARITYERR		
Value	Description									
0	NOPARITYERR									
1	PARITYERR									
1	oe	<p>Overrun error bit. This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and a new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost.</p> <p>0 = no overrun error 1 = overrun error Reading the LSR clears the OE bit.</p> <table><tr><th>Value</th><th>Description</th></tr><tr><td>0</td><td>NOOVERRUN</td></tr><tr><td>1</td><td>OVERRUN</td></tr></table>	Value	Description	0	NOOVERRUN	1	OVERRUN	RO	0x0

22.6.1.9. msr

Modem Status Register
It should be noted that whenever bits 0, 1, 2 or 3 is set to logic one, to indicate a change on the modem control inputs, a modem status interrupt will be generated

if enabled via the IER regardless of when the change occurred. Since the delta bits (bits 0, 1, 3) can get set after a reset if their respective modem signals are active (see individual bits for details), a read of the MSR after reset can be performed to prevent unwanted interrupts.

srbr_sthr_0 Fields

Bit	Name	Description	Access	Reset
31:8	rsvd_srbr_sthr_0_31to8	Reserved bits [31:8] - Read Only	RO	0x0
7:0	srbr_sthr_0	<p>This is shadow register for RBR and THR and has been allocated sixteen 32-bit locations so as to accommodate burst accesses from the master.</p> <p>srbr : This register contains the data byte received on the serial input port (sin) in UART mode or the serial infrared input (sir_in) in infrared mode. The data in this register is valid only if the Data Ready (DR) bit in the Line status Register (LSR) is set. If in non-FIFO mode (FIFO_MODE == NONE) or FIFOs are disabled (FCR[0] set to zero), the data in the RBR must be read before the next data arrives, otherwise it is overwritten, resulting in an overrun error. If in FIFO mode (FIFO_MODE != NONE) and FIFOs are enabled (FCR[0] set to one), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO are preserved, but any incoming data is lost. An overrun error also occurs.</p> <p>sthr: This register contains data to be transmitted on the serial output port (sout) in UART mode or the serial infrared output (sir_out_n) in infrared mode. Data should only be written to the THR when the THR Empty (THRE) bit (LSR[5]) is set. If in non-FIFO mode or FIFOs are disabled (FCR[0] set to zero) and THRE is set, writing a single character to the THR clears the THRE. Any additional writes to the THR before the THRE is set again causes the THR data to be overwritten. If in FIFO mode and FIFOs are enabled (FCR[0] set to one) and THRE is set, x number of characters of data may be written to the THR before the FIFO is full. The number x (default=16) is determined by the value of FIFO Depth that you set during configuration. Any attempt to write data when the FIFO is full results in the write data being lost.</p>	RO	0x0

1	NOTFULL							
0	rsvd_busy	<p>UART Busy. This bit is only valid when UART_16550_COMPATIBLE == NO. This indicates that a serial transfer is in progress, when cleared indicates that the DW_apb_uart is idle or inactive. 0 = DW_apb_uart is idle or inactive 1 - DW_apb_uart is busy (actively transferring data) Note that it is possible for the UART Busy bit to be cleared even though a new character may have been sent from another device. That is, if the DW_apb_uart has no data in the THR and RBR and there is no transmission in progress and a start bit of a new character has just reached the DW_apb_uart. This is due to the fact that a valid start is not seen until the middle of the bit period and this duration is dependent on the baud divisor that has been programmed. If a second system clock has been implemented (CLOCK_MODE == Enabled) the assertion of this bit will also be delayed by several cycles of the slower clock.</p>	RO	0x0

23. General-Purpose I/O Interface

The hard processor system (HPS) provides three general-purpose I/O (GPIO) interface modules. The GPIO modules are instances of the Synopsys DesignWare APB General Purpose Programming I/O (DW_apb_gpio) peripheral.[†] ⁽⁵⁷⁾

Related Information

[Intel Arria 10 Hard Processor System Technical Reference Manual Revision History](#) on page 17

For details on the document revision history of this chapter

23.1. Features of the GPIO Interface

The GPIO interface offers the following features:

- Supports digital debounce
- Configurable interrupt mode
- Supports up to 62 I/O pins

23.2. GPIO Interface Block Diagram and System Integration

The figure below shows a block diagram of the GPIO interface. The following table shows a pin table of the GPIO interface:

Figure 184. Arria 10 SoC GPIO

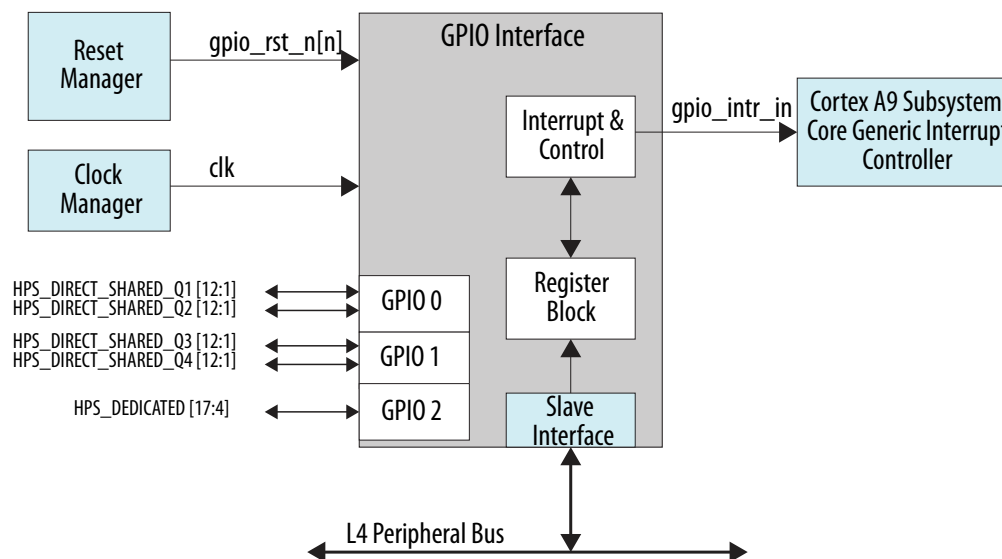

Table 253. GPIO Interface pin table

Pin Name	Mapped to GPIO Signal Name	Comments
HPS_DIRECT_SHARED_Q1 [12:1]	GPIO 0 [11:0]	Shared Input / Output
HPS_DIRECT_SHARED_Q2 [12:1]	GPIO 0 [23:12]	Shared Input / Output
HPS_DIRECT_SHARED_Q3 [12:1]	GPIO 1 [11:0]	Shared Input / Output
HPS_DIRECT_SHARED_Q4 [12:1]	GPIO 1 [23:12]	Shared Input / Output
HPS_DEDICATED [17:4]	GPIO 2 [13:0]	Dedicated Input / Output

23.3. Functional Description of the GPIO Interface

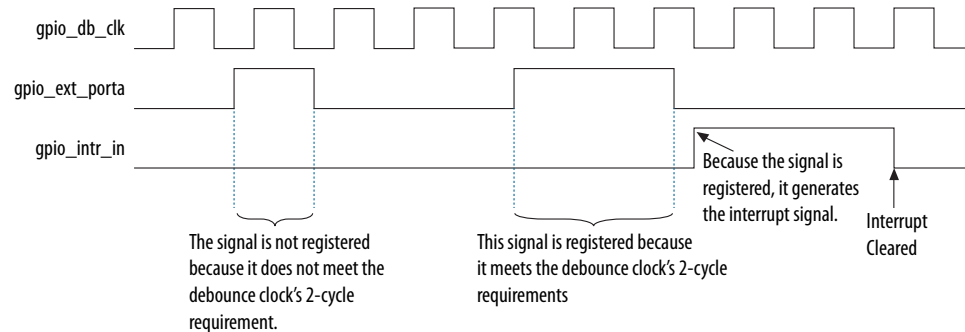

23.3.1. Debounce Operation

The GPIO modules provided in the HPS include optional debounce capabilities. The external signal can be debounced to remove any spurious glitches that are less than one period of the external debouncing clock, `gpio_db_clk`. †

When input signals are debounced using the `gpio_db_clk` debounce clock, the signals must be active for a minimum of two cycles of the debounce clock to guarantee that they are registered. Any input pulse widths less than a debounce clock period are filtered out. If the input signal pulse width is between one and two debounce clock widths, it may or may not be filtered out, depending on its phase relationship to the debounce clock. If the input pulse spans two rising edges of the debounce clock, it is registered. If it spans only one rising edge, it is not registered. †

The figure below shows a timing diagram of the debounce circuitry for both cases: a bounced input signal, and later, a propagated input signal.

Figure 185. Debounce Timing With Asynchronous Reset Flip-Flops

Note: Enabling the debounce circuitry increases interrupt latency by two clock cycles of the debounce clock.

23.3.2. Pin Directions

All GPIO pins can be configured to be either input or output signals.

23.3.3. Taking the GPIO Interface Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

23.4. GPIO Interface Programming Model

Debounce capability for each of the input signals can be enabled or disabled under software control by setting the corresponding bits in the `gpio_debounce` register, accordingly. The debounce clock must be stable and operational before the debounce capability is enabled.

Under software control, the direction of the external I/O pad is controlled by a write to the `gpio_swportx_ddr` register. When configured as input mode, reading `gpio_ext_porta` would read the values on the signal of the external I/O pad. When configured as output mode, the data written to the `gpio_swporta_dr` register drives the output buffer of the I/O pad. The same pins are shared for both input and output modes, so they cannot be configured as input and output modes at the same time. †

23.5. General-Purpose I/O Interface Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the [Arria 10 HPS Address Map and Register Definitions](#).

23.5.1. gpio Address Map

Module Instance	Base Address	End Address
i_gpio_0_gpio	0xFFC02900	0xFFC029FF
i_gpio_1_gpio	0xFFC02A00	0xFFC02AFF
i_gpio_2_gpio	0xFFC02B00	0xFFCF9FFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

23.5.1.2. gpio_swporta_dr

```
Name: Port A data register
set_attribute $reg -attr RALAttribute -sub NO_BIT_BASH_TEST -value 1
Size: 1-32 bits
Address Offset: 0x00
Read/Write Access: Read/Write
```

Module Instance	Base Address	Register Address
i_gpio_0_gpio	0xFFC02900	0xFFC02900
i_gpio_1_gpio	0xFFC02A00	0xFFC02A00
i_gpio_2_gpio	0xFFC02B00	0xFFC02B00

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

24. Timer

The hard processor system (HPS) provides four 32-bit general-purpose timers connected to the level 4 (L4) peripheral bus. The timers optionally generate an interrupt when the 32-bit binary count-down timer reaches zero. The timers are instances of the Synopsys DesignWare APB Timers (DW_apb_timers) peripheral. ⁽⁵⁸⁾

Related Information

- [Cortex-A9 Microprocessor Unit Subsystem](#) on page 1022
The MPU subsystem provides additional timers. For more information about the timers in the MPU, refer to the *Cortex-A9 MPU* chapter.
- [Intel Arria 10 Hard Processor System Technical Reference Manual Revision History](#) on page 17
For details on the document revision history of this chapter

24.1. Features of the Timer

- Supports interrupt generation
- Supports free-running mode
- Supports user-defined count mode

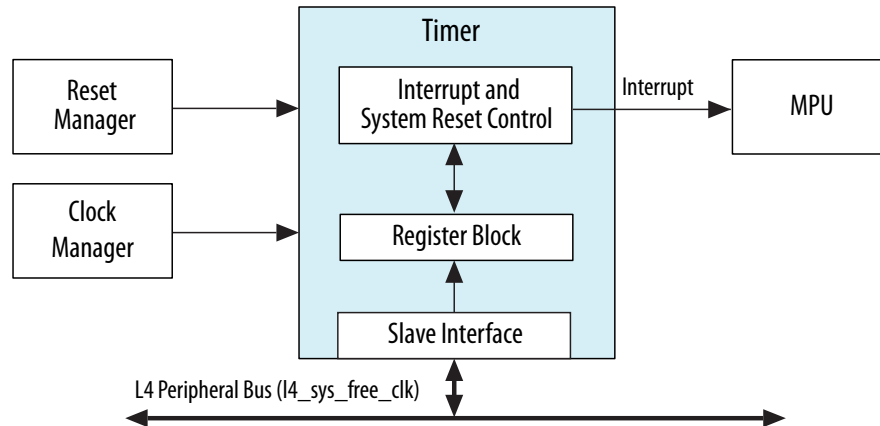

24.2. Timer Block Diagram and System Integration

Each timer includes a slave interface for control and status register (CSR) access, a register block, and a programmable 32-bit down counter that generates interrupts on reaching zero. The timer operates on a single clock domain driven by the clock manager.

Figure 186. Timer Block Diagram

24.3. Functional Description of the Timer

The 32-bit timer counts down from a programmed value and generates an interrupt when the count reaches zero. The timer has an independent clock input connected to the system clock signal or to an external clock source. †

The timer supports the following modes of operation:

- Free-running mode—decrementing from the maximum value (0xFFFFFFFF). Reloads maximum value upon reaching zero.
- User-defined count mode—generates a periodic interrupt. Decrements from the user-defined count value loaded from the timer1 load count register (`timer1loadcount`). Reloads the user-defined count upon reaching zero.

The initial value for the timer (that is, the value from which it counts down) is loaded into the timer by the `timer1loadcount` register. The following events can cause a timer to load the initial count from the `timer1loadcount` register: †

- Timer is enabled after being reset or disabled
- Timer counts down to 0

24.3.1. Clocks

Table 254. Timer Clock Characteristics

Timer		System Clock	Notes
System timer 0	sys_timer0	l4_sys_free_clk	—
System timer 1	sys_timer1		
SP timer 0	sp_timer0	l4_sp_clk	Timer must be disabled if clock frequency changes
SP timer 1	sp_timer1		

The timers above are labeled according to the clock they receive. The system timers are connected to the L4_SYS bus and clocked by the l4_sys_free_clk. The SP timers are connected to the L4_SP bus and clocked by l4_sp_clk.

SP timer 0 and SP timer 1 must be disabled before l4_sp_clk is changed to another frequency. You can then re-enable the timer once the clock frequency change takes effect.

Related Information

[Clock Manager](#) on page 56

For more information about clock performance, refer to the *Clock Manager* chapter.

24.3.2. Resets

The timers are reset by a cold or warm reset. Resetting the timers produces the following results in the following order:

1. The timer is disabled.
2. The interrupt is enabled.
3. The timer enters free-running mode.
4. The timer count load register value is set to zero.

24.3.3. Interrupts

The timer1 interrupt status (timer1lintstat) and timer1 end of interrupt (timer1eoi) registers handle the interrupts. The timer1lintstat register allows you to read the status of the interrupt. Reading from the timer1eoi register clears the interrupt. †

The timer1 control register (timer1controlreg) contains the timer1 interrupt mask bit (timer1_interrupt_mask) to mask the interrupt. In both the free-running and user-defined count modes of operation, the timer generates an interrupt signal when the timer count reaches zero and the interrupt mask bit of the control register is high.

If the timer interrupt is set, then it is cleared when the timer is disabled.

24.4. Timer Programming Model

24.4.1. Initialization

To initialize the timer, perform the following steps: †

1. Initialize the timer through the `timer1controlreg` register: †
 - Disable the timer by writing a 0 to the `timer1_enable` bit (`timer1_enable`) of the `timer1controlreg` register. †

Note: Before writing to a timer1 load count register (`timer1loadcount`), you must disable the timer by writing a 0 to the `timer1_enable` bit of the `timer1controlreg` register to avoid potential synchronization problems. †

 - Program the timer mode—user-defined count or free-running—by writing a 0 or 1, respectively, to the `timer1_mode` bit (`timer1_mode`) of the `timer1controlreg` register. †
 - Set the interrupt mask as either masked or not masked by writing a 1 or 0, respectively, to the `timer1_interrupt_mask` bit of the `timer1controlreg` register. †
2. Load the timer counter value into the `timer1loadcount` register. †
3. Enable the timer by writing a 1 to the `timer1_enable` bit of the `timer1controlreg` register. †

24.4.2. Enabling the Timer

When a timer transitions to the enabled state, the current value of `timer1loadcount` register is loaded into the timer counter. †

1. To enable the timer, write a 1 to the `timer1_enable` bit of the `timer1controlreg` register.

24.4.3. Disabling the Timer

When the timer enable bit is cleared to 0, the timer counter and any associated registers in the timer clock domain, are asynchronously reset. †

1. To disable the timer, write a 0 to the `timer1_enable` bit. †

24.4.4. Loading the Timer Countdown Value

When a timer counter is enabled after being reset or disabled, the count value is loaded from the `timer1loadcount` register; this occurs in both free-running and user-defined count modes. †

When a timer counts down to 0, it loads one of two values, depending on the timer operating mode: †

- User-defined count mode—timer loads the current value of the `timer1loadcount` register. Use this mode if you want a fixed, timed interrupt. Designate this mode by writing a 1 to the `timer1_mode` bit of the `timer1controlreg` register. †
- Free-running mode—timer loads the maximum value (0xFFFFFFFF). The timer max count value allows for a maximum amount of time to reprogram or disable the timer before another interrupt occurs. Use this mode if you want a single timed interrupt. Enable this mode by writing a 0 to the `timer1_mode` bit of the `timer1controlreg` register. †

24.4.5. Servicing Interrupts

24.4.5.1. Clearing the Interrupt

An active timer interrupt can be cleared in two ways.

1. If you clear the interrupt at the same time as the timer reaches 0, the interrupt remains asserted. This action happens because setting the timer interrupt takes precedence over clearing the interrupt. †
2. To clear an active timer interrupt, read the `timerleoi` register or disable the timer. When the timer is enabled, its interrupt remains asserted until it is cleared by reading the `timerleoi` register. †

24.4.5.2. Checking the Interrupt Status

You can query the interrupt status of the timer without clearing its interrupt.

1. To check the interrupt status, read the `timerlintstat` register. †

24.4.5.3. Masking the Interrupt

The timer interrupt can be masked using the `timer1controlreg` register.

To mask an interrupt, write a 1 to the `timer1_interrupt_mask` bit of the `timer1controlreg` register. †

24.5. Timer Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the [Arria 10 HPS Address Map and Register Definitions](#).

24.5.1. timer_sys Address Map

Module Instance	Base Address	End Address
i_timer_sys_0_timer	0xFFD00000	0xFFD000FF
i_timer_sys_1_timer	0xFFD00100	0xFFD001FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

24.5.1.2. timer1loadcount

Name: Timer1 Load Count Register
Size: 8-32 bits
Address Offset: 0x00
Read/Write Access: Read/Write

Module Instance	Base Address	Register Address
i_timer_sys_0_timer	0xFFD00000	0xFFD00000
i_timer_sys_1_timer	0xFFD00100	0xFFD00100

Offset: 0x0

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
timer1loadcount RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
timer1loadcount RW 0x0															

timer1loadcount Fields

Bit	Name	Description	Access	Reset
31:0	timer1loadcount	Value to be loaded into Timer1. This is the value from which counting commences. Any value written to this register is loaded into the associated timer.	RW	0x0

24.5.1.3. timer1currentval

Name: Timer1 Current Value
Size: 8-32 bits
Address Offset: 4
Read/Write Access: Read

Module Instance	Base Address	Register Address
i_timer_sys_0_timer	0xFFD00000	0xFFD00004
i_timer_sys_1_timer	0xFFD00100	0xFFD00104

Offset: 0x4

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
timer1currentval RO 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
timer1currentval RO 0x0															

timer1currentval Fields

Bit	Name	Description	Access	Reset
31:0	timer1currentval	Current Value of Timer1. This register is supported only when timer1_clk is synchronous to pclk. Reading this register when using independent clocks results in an undefined value.	RO	0x0

24.5.1.4. timer1controlreg

Name: Timer1 Control Register
Size: 3 bits
Address Offset: 8
Read/Write Access: Read/Write
This register controls enabling, operating mode (free-running or defined-count), and interrupt mask of Timer1. You can program each Timer1ControlReg to enable or disable a specific timer and to control its mode of operation.

Module Instance	Base Address	Register Address
i_timer_sys_0_timer	0xFFD00000	0xFFD00008
i_timer_sys_1_timer	0xFFD00100	0xFFD00108

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

24.5.2.4. timer1controlreg

Name: Timer1 Control Register
 Size: 3 bits
 Address Offset: 8
 Read/Write Access: Read/Write
 This register controls enabling, operating mode (free-running or defined-count), and interrupt mask of Timer1. You can program each Timer1ControlReg to enable or disable a specific timer and to control its mode of operation.

Module Instance	Base Address	Register Address
i_timer_sp_0_timer	0xFFC02700	0xFFC02708
i_timer_sp_1_timer	0xFFC02800	0xFFC02808

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

25. Watchdog Timer

The watchdog timers are peripherals you can use to recover from system lockup that might be caused by software or system related issues. The hard processor system (HPS) provides two programmable watchdog timers, which are connected to the level 4 (L4) peripheral bus. The watchdog timers are instances of the Synopsys DesignWare APB Watchdog Timer (DW_apb_wdt) peripheral. ⁽⁵⁹⁾

The microprocessor unit (MPU) subsystem provides two additional watchdog timers.

For more information about the watchdog timers in the MPU, refer to *Cortex A9 Microprocessor Unit Subsystem* chapter.

25.1. Features of the Watchdog Timer

The following list describes the features of the watchdog timer:

- Programmable 32-bit timeout range
- Timer counts down from a preset value to zero, then performs one of the following user-configurable operations:
 - Generates a system reset †
 - Generates an interrupt, restarts the timer, and if the timer is not cleared before a second timeout occurs, generates a system reset
- Dual programmable timeout period, used when the time to wait after the first start is different than that required for subsequent restarts †
- Prevention of accidental restart of the watchdog counter †
- Prevention of accidental disabling of the watchdog counter †
- Pause mode for debugging

25.2. Watchdog Timer Block Diagram and System Integration

Each watchdog timer consists of a slave interface for control and status register (CSR) access, a register block, and a 32-bit down counter that operates on the slave interface clock (l4_sys_free_clk). A pause input, driven by the system manager, optionally pauses the counter when a CPU is being debugged.

The watchdog timer drives an interrupt request to the MPU and a reset request to the reset manager.

Figure 187. Watchdog Timer Block Diagram

25.3. Functional Description of the Watchdog Timer

25.3.1. Watchdog Timer Counter

Each watchdog timer is a programmable, little-endian down counter that decrements by one on each clock cycle. The watchdog timer supports 16 fixed timeout period values. Software chooses which timeout periods are desired. A timeout period is $2^{<n>l4_sys_free_clk}$ clock periods, where n is an integer from 16 to 31 inclusive.

Software must regularly restart the timer (which reloads the counter with the restart timeout period value) to indicate that the system is functioning normally. Software can reload the counter at any time by writing to the restart register. If the counter reaches zero, the watchdog timer has timed out, indicating an unrecoverable error has occurred and a system reset is needed.

Software configures the watchdog timer to one of the following output response modes:

- On timeout, generate a reset request.
- On timeout, assert an interrupt request and restart the watchdog timer. Software must service the interrupt and reset the watchdog timer before a second timeout occurs. Otherwise, generate a reset request.

If a restart occurs at the same time the watchdog counter reaches zero, an interrupt is not generated.

Note: After the watchdog timer reaches zero and generates a reset or interrupt, the counter resets and continues to count.

Related Information

- [Watchdog Timer Clocks](#) on page 4412
- [Setting the Timeout Period Values](#) on page 4413
- [Selecting the Output Response Mode](#) on page 4413
- [Reloading a Watchdog Counter](#) on page 4414

25.3.2. Watchdog Timer Pause Mode

The watchdog timers can be paused during debugging. The watchdog timer pause mode is controlled by the system manager. The following options are available:

- Pause the timer while either CPU0 or CPU1 is in debug mode
- Pause the timer while only CPU1 is in debug mode
- Pause the timer while only CPU0 is in debug mode
- Do not pause the timer

When pause mode is enabled, the system manager pauses the watchdog timer while debugging. When pause mode is disabled, the watchdog timer runs while debugging.

At reset, the watchdog pausing feature is enabled for both CPUs by default.

Related Information

[Pausing a Watchdog Timer](#) on page 4414

25.3.3. Watchdog Timer Clocks

Each watchdog timer is connected to the `l4_sys_free_clk` clock so that timer operation is not dependent on the phase-locked loops (PLLs) in the clock manager and so that it is always running. This independence allows recovery from software that inadvertently programs the PLLs in the clock manager incorrectly.

Table 255. Watchdog Timer Clocks

Timer	System Clock
watchdog0	l4_sys_free_clk
watchdog1	l4_sys_free_clk

Related Information

[Clock Manager](#) on page 56

For more information, refer to the *Clock Manager* chapter.

25.3.4. Watchdog Timer Resets

Watchdog timers are reset by a cold or warm reset from the reset manager, and are disabled when exiting reset. †

Related Information

[Reset Manager](#) on page 138

For more information, refer to the *Reset Manager* chapter.

25.3.4.1. Taking the Watchdog Timer Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

25.4. Watchdog Timer Programming Model

25.4.1. Setting the Timeout Period Values

The watchdog timers have a dual timeout period. The counter uses the initial start timeout period value the first the timer is started. All subsequent restarts use the restart timeout period. The valid values are $2^{(16+i)} - 1$ clock cycles, where i is an integer from 0 to 15. To set the programmable timeout periods, perform the following actions in no specific order:

Note: Set the timeout values before enabling the timer.

- To set the initial start timeout period, write i to the timeout period for the initialization field (`top_init`) of the watchdog timeout range register (`wdt_torr`).
- To set the restart timeout period, write i to the timeout period field (`top`) of the `wdt_torr` register

25.4.2. Selecting the Output Response Mode

The watchdog timers have two output response modes. To select the desired mode, perform one of the following actions:

- To generate a system reset request when a timeout occurs, write 0 to the output response mode bit (`rmod`) of the watchdog timer control register (`wdt_cr`).
- To generate an interrupt and restart the timer when a timeout occurs, write 1 to the `rmod` field of the `wdt_cr` register.

If a restart occurs at the same time the watchdog counter reaches zero, a system reset is not generated. †

Related Information

[Watchdog Timer Counter](#) on page 4411

25.4.3. Enabling and Initially Starting a Watchdog Timer

To enable and start a watchdog timer, write the value 1 to the watchdog timer enable bit (`wdt_en`) of the `wdt_cr` register.

25.4.4. Reloading a Watchdog Counter

To reload a watchdog counter, write the value 0x76 to the counter restart register (`wdt_crr`). This unique 8-bit value is used as a safety feature to prevent accidental restarts.

25.4.5. Pausing a Watchdog Timer

Pausing the watchdog timers is controlled by the L4 watchdog debug register (`wddbgr`) in the system manager.

Related Information

[Features of the System Manager](#) on page 244

For more information, refer to the *System Manager* chapter.

25.4.6. Disabling and Stopping a Watchdog Timer

The watchdog timers are disabled and stopped by resetting them from the reset manager.

Related Information

[Reset Manager](#) on page 138

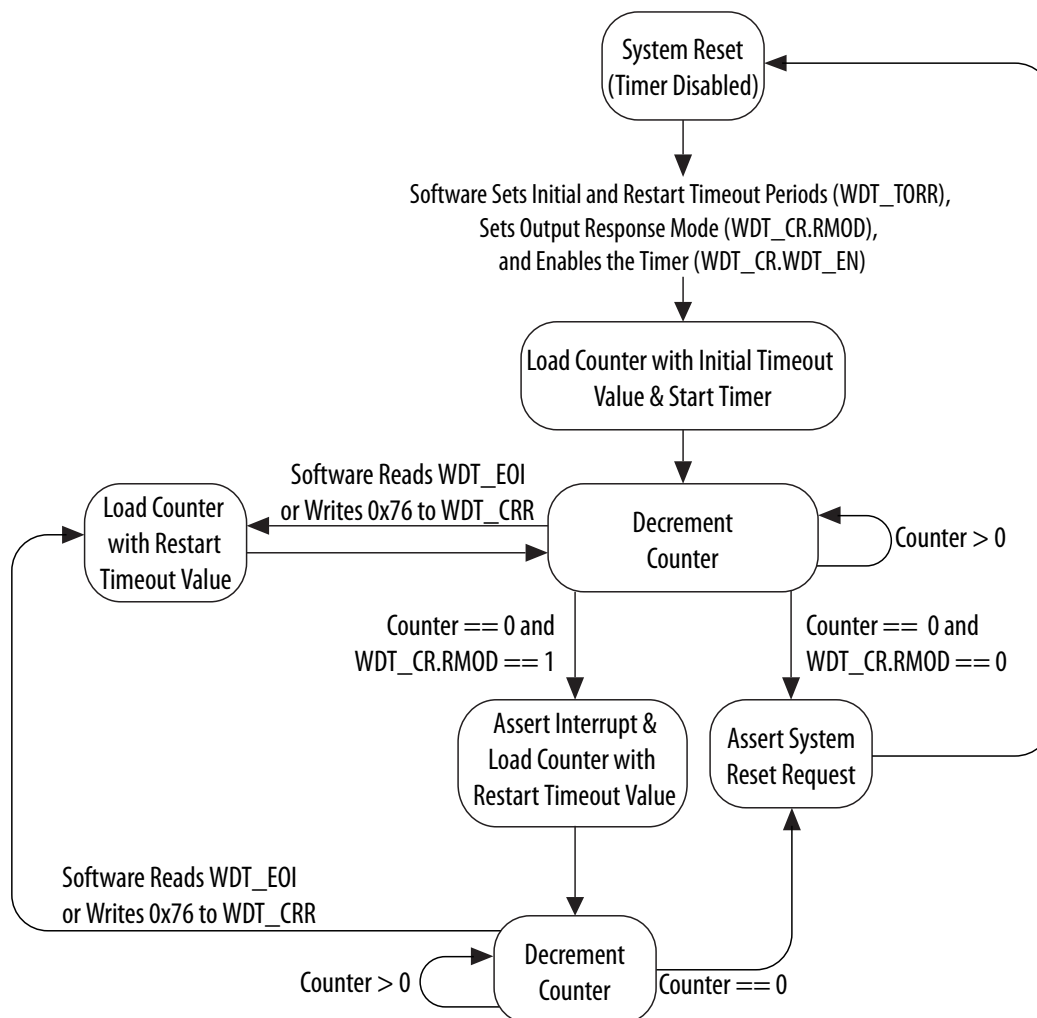

For more information, refer to the *Reset Manager* chapter.

25.4.7. Watchdog Timer State Machine

The following figure illustrates the behavior of the watchdog timer, including the behavior of both output response modes. Once initialized, the counter decrements at every clock cycle. The state machine remains in the Decrement Counter state until the counter reaches zero, or the watchdog timer is restarted. If software reads the interrupt clear register (`wdt_eoi`), or writes 0x76 to the `wdt_crr` register, the state changes from Decrement Counter to Load Counter with Restart Timeout Value. In this state, the watchdog counter gets reloaded with the restart timeout value, and then the state changes back to Decrement Counter.

Figure 188. Watchdog Timer State Machine

If the counter reaches zero, the state changes based on the value of the output response mode setting defined in the `rmod` bit of the `wdt_cr` register. If the `rmod` bit of the `wdt_cr` register is 0, the output response mode is to generate a system reset request. In this case, the state changes to Assert System Reset Request. In response, the reset manager resets and disables the watchdog timer, and gives software the opportunity to reinitialize the timer.

If the `rmod` bit of the `wdt_cr` register is 1, the output response mode is to generate an interrupt. In this case, the state changes to Assert Interrupt and Load Counter with Restart Timeout Value. An interrupt to the processor is generated, and the watchdog counter is reloaded with the restart timeout value. The state then changes to the second Decrement Counter state, and the counter resumes decrementing. If software reads the `wdt_eoi` register, or writes 0x76 to the `wdt_crr` register, the state changes from Decrement Counter to Load Counter with Restart Timeout Value. In this state, the watchdog counter gets reloaded with the restart timeout value, and then the state changes back to the first Decrement Counter state. If the counter again

reaches zero, the state changes to Assert System Reset Request. In response, the reset manager resets the watchdog timer, and gives software the opportunity to reinitialize the timer.

25.5. Watchdog Timer Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the [Arria 10 HPS Address Map and Register Definitions](#).

25.5.1. watchdog Address Map

26. Hard Processor System I/O Pin Multiplexing

The Arria 10 SoC has two banks of flexible I/O pins that are used for hard processor system (HPS) operation, external memory and external peripheral connection. Some of the pins are dedicated to the HPS, and others can be shared with the FPGA fabric. A pin multiplexing mechanism allows the SoC to use the flexible I/O pins in a wide range of configurations.

Related Information

[Intel Arria 10 Hard Processor System Technical Reference Manual Revision History](#) on page 17

For details on the document revision history of this chapter

26.1. Features of the HPS I/O Block

The I/O block provides the following functionality and features:

- I/O pins
 - Dedicated I/O – 17 pins supporting clock, resets, boot devices, and other key peripherals.
 - Shared I/O – 48 pins available for HPS external memory and peripherals. Shared I/O pins can also be used by FPGA logic.

Note: The HPS also interfaces with an SDRAM memory controller. This interface is separate from the dedicated and shared I/O pins discussed in this chapter.

- I/O multiplexing
 - Selects pins used by each HPS peripheral
 - Can assign shared I/O pins to FPGA logic
 - Can expose HPS peripheral interfaces to FPGA logic

Note: When routed to the FPGA, some HPS peripherals require additional pipeline support in the connected soft logic. Refer to the relevant HPS peripheral chapter for details.

I/O multiplexing is configured when you instantiate the HPS component.

26.2. HPS I/O Block Diagram and System Integration

The HPS I/O block consists of the following subblocks:

- Dedicated pin multiplexers (MUXes) – MUXes for the dedicated I/O bank
- Shared pin multiplexers – MUXes for the shared I/O bank
- FPGA access pin multiplexers – MUXes for HPS peripheral connections to the FPGA fabric
- Register slave interface – Provides access to control registers, which allow the bootloader to initialize I/O pins and HPS peripheral interfaces at system startup

26.3. Functional Description of the HPS I/O

26.3.1. Dedicated I/O Pins

The HPS has 17 dedicated I/O pins. Three are used as clock, cold reset and warm reset. The remaining 14 dedicated I/O pins are dedicated to boot devices and other commonly-used peripherals. The following HPS peripherals can be served by dedicated I/O pins:

- GPIO2
- NAND
- SD/MMC
- QSPI
- CM_PLL
- UART1
- SPI0
- EMAC0 MDIO interface
- EMAC1 MDIO interface
- EMAC2 MDIO interface

Each of these peripherals can alternatively be routed through the FPGA. You can configure this routing when you instantiate the HPS component.

26.3.1.1. Warm Reset Pin

The warm reset signal is a bidirectional signal; a warm reset event can drive into the HPS, or a warm reset event can be generated by the HPS and drive out of this pin.

26.3.1.2. Boot Pins

The following dedicated I/O pins convey boot source information:

- HPS_DEDICATED_6/BOOTSEL2
- HPS_DEDICATED_10/BOOTSEL1
- HPS_DEDICATED_11/BOOTSEL0

Typically, software samples these pins at cold reset.

Pinout files for Arria 10 devices

26.3.2. Shared I/O Pins

There are 48 HPS peripheral pins that are shared with the FPGA core. They are divided into four quadrants of 12 signals per quadrant. Each quadrant can be assigned to the HPS or the FPGA fabric.

In each shared I/O quadrant, all 12 I/Os are assigned either to the FPGA or to the HPS. It is not possible to divide the I/Os in a quadrant between the FPGA and HPS.

When a quadrant is assigned to the FPGA fabric, you can connect FPGA soft logic to the shared I/O pins with the assignment editor, just as for any other FPGA I/O pins. Soft logic can use the shared I/O pins to interface to off-chip resources. However, pins in that quadrant are no longer directly available to HPS peripherals. Enabled HPS peripherals can be assigned to another quadrant, or else their interfaces can be routed to the FPGA fabric.

The following HPS peripherals can be assigned to shared I/O pins:

- EMAC0
- EMAC1
- EMAC2
- GPIO0
- GPIO1
- I2C0
- I2C1
- NAND
- QSPI
- SD/MMC
- SPI0
- SPI1
- TRACE
- UART0
- UART1
- USB0
- USB1

Each of these peripherals except USB0 and USB1 can alternatively be routed through the FPGA. You configure this routing when you instantiate the HPS component in Platform Designer.

Note: Although the shared I/O pins are configured through the control registers, software cannot reconfigure the shared I/O pins after I/O configuration is complete. There is no support for dynamically changing the pin MUX selections for shared pins.

26.3.3. FPGA Access

Most HPS peripheral interfaces can be connected into the FPGA fabric, instead of to the dedicated or shared I/O pins.

HPS peripherals connect to the FPGA fabric through the FPGA access pin MUX. When connected to the FPGA fabric, peripheral interfaces are exposed as ports of the HPS component.

Connecting HPS peripherals to the FPGA fabric can be a strategy to make optimal use of the I/O pins available to the HPS. For example, you can route HPS peripherals through the FPGA if your design requires more I/Os than the HPS I/O block provides.

All HPS peripherals except the USB 2.0 OTG controllers can interface to the FPGA fabric.

Related Information

[Configuring HPS I/O Multiplexing](#) on page 4443
Information about configuring the HPS I/O MUXes

26.3.4. Control Registers

The HPS provides control registers that allow the system to initialize the following I/O parameters at system startup:

- Pins assigned to each HPS peripheral
- Shared I/O pins optionally assigned to FPGA logic
- HPS peripheral interfaces optionally exposed to FPGA logic
- I/O cell configuration

The HPS I/O control registers can only be accessed in secure mode.

Control registers can be divided into the following groups:

- Dedicated pin MUX registers
- Dedicated configuration registers
- Shared pin MUX registers
- FPGA access MUX registers

You set up the control registers when you instantiate the HPS component at the time of system generation. When you configure the HPS component, Platform Designer determines the correct register settings, and places them in the Intel Quartus Prime I/O programming file.

- [I/O Pin MUX Address Map and Register Definitions for Arria 10](#) on page 4444
- [Configuring HPS I/O Multiplexing](#) on page 4443
Information about configuring the HPS I/O MUXes

26.3.4.1. Dedicated Pin MUX Registers

Dedicated pin MUX registers control the functions of the dedicated pins. One register is provided for each dedicated I/O pin.

The HPS provides pin MUX registers, `pinmux_dedicated_io_4` through `pinmux_dedicated_io_17`, for each of the dedicated pins `HPS_DEDICATED_4` through `HPS_DEDICATED_17`. Each pin MUX register contains a 4-bit MUX select field to select the function of the dedicated pin. At a cold reset event these fields are reset to 15, selecting a general purpose I/O function. A warm reset event does not affect these registers.

The registers for dedicated I/O pins `HPS_DEDICATED_1` through `HPS_DEDICATED_3` provide no functionality, because these pins are always used as the HPS clock and reset pins.

Note: Although the dedicated I/O pins are configured through the control registers, Intel recommends against reconfiguring the dedicated I/O pins after I/O configuration is complete.

- [Arria 10 Hard Processor System Pin Information spreadsheet](#)
Details of available HPS pin MUXing options
- [Pin-Out Files for Intel Devices](#)
Pinout files for Arria 10 devices

26.3.4.2. Dedicated Configuration Registers

Configuration registers for each dedicated I/O pin allow software to control the corresponding I/O cell. These registers, `configuration_dedicated_io_1` through `configuration_dedicated_io_17`, allow software to set the following characteristics:

- Termination
- Slew rate
- Input buffer settings

These registers are not affected by a warm reset.

One configuration register, `configuration_dedicated_io_bank`, is also provided to select the I/O voltage for the dedicated I/O bank. At cold reset this register defaults to 0x2 (2.5-3.0 volt operation). This register is not affected by a warm reset.

Typically, the boot code programs this register when the system boots up. The boot code reads the BOOTSEL0, BOOTSEL1, and BOOTSEL2 pins and then sets the dedicated I/O bank to either 1.8 or 2.5-3.0 volt operation, depending on the pin status.

Note: Although the dedicated I/O pins are configured through the control registers, Intel recommends against reconfiguring the dedicated I/O pins after I/O configuration is complete.

- [I/O Pin MUX Address Map and Register Definitions for Arria 10](#) on page 4444
- [Configuring HPS I/O Multiplexing](#) on page 4443
Information about configuring the HPS I/O MUXes

26.3.4.3. Shared Pin MUX Registers

There are 48 shared pin MUX registers, one for each shared I/O pin. The pin MUX register names correspond to the signal names, as listed in the following table.

Table 256. Shared Pin MUX Register Names and Signals

Shared Pin MUX Register Name	HPS Signal Name	FPGA Signal Name
<code>pinmux_shared_io_q1_1</code>	<code>HPS_SHARED_IO_Q1_1</code>	<code>FPGA_SHARED_IO_Q1_1</code>
...
<code>pinmux_shared_io_q1_12</code>	<code>HPS_SHARED_IO_Q1_12</code>	<code>FPGA_SHARED_IO_Q1_12</code>
<code>pinmux_shared_io_q2_1</code>	<code>HPS_SHARED_IO_Q2_1</code>	<code>FPGA_SHARED_IO_Q2_1</code>
...
<code>pinmux_shared_io_q2_12</code>	<code>HPS_SHARED_IO_Q2_12</code>	<code>FPGA_SHARED_IO_Q2_12</code>
<code>pinmux_shared_io_q3_1</code>	<code>HPS_SHARED_IO_Q3_1</code>	<code>FPGA_SHARED_IO_Q3_1</code>
...
<code>pinmux_shared_io_q3_12</code>	<code>HPS_SHARED_IO_Q3_12</code>	<code>FPGA_SHARED_IO_Q3_12</code>
<i>continued...</i>		

Shared Pin MUX Register Name	HPS Signal Name	FPGA Signal Name
pinmux_shared_io_q4_1	HPS_SHARED_IO_Q4_1	FPGA_SHARED_IO_Q4_1
...
pinmux_shared_io_q4_12	HPS_SHARED_IO_Q4_12	FPGA_SHARED_IO_Q4_12

Each shared pin MUX register contains a 4-bit MUX select field to select the function of the shared I/O pin. At a cold reset event these fields default to 15, selecting a general purpose I/O function. A warm reset event does not affect these registers.

Note: Although the shared I/O pins are configured through the control registers, software cannot reconfigure the shared I/O pins after I/O configuration is complete. There is no support for dynamically changing the pin MUX selections for shared pins.

26.3.4.4. FPGA Access MUX Registers

The FPGA access ("use FPGA") MUX registers select whether each HPS peripheral uses HPS I/O pins or is routed to the FPGA fabric.

All peripherals except the USBs can be routed to the FPGA. The following FPGA access registers are available:

- pinmux_emac0_usefpga
- pinmux_emac1_usefpga
- pinmux_emac2_usefpga
- pinmux_i2c0_usefpga
- pinmux_i2c1_usefpga
- pinmux_i2c_emac0_usefpga
- pinmux_i2c_emac1_usefpga
- pinmux_i2c_emac2_usefpga
- pinmux_nand_usefpga
- pinmux_qspi_usefpga
- pinmux_sdmmc_usefpga
- pinmux_spim0_usefpga
- pinmux_spim1_usefpga
- pinmux_spis0_usefpga
- pinmux_spis1_usefpga
- pinmux_uart0_usefpga

- `pinmux_uart1_usefpga`
- `pinmux_mdio0_usefpga`
- `pinmux_mdio1_usefpga`
- `pinmux_mdio2_usefpga`

At cold reset, the FPGA access registers default to 0, selecting the HPS I/O pins. These registers are not affected by a warm reset event.

Note: Although the FPGA access MUX is configured through the control registers, Intel recommends against reconfiguring the FPGA access MUX after I/O configuration is complete.

Information about configuring the HPS I/O MUXes

26.3.5. Configuring HPS I/O Multiplexing

HPS I/O multiplexing is configured when the system is generated with Platform Designer.

Related Information

[Configuring Peripheral Pin Multiplexing](#) on page 4589

For information about configuring the HPS I/O MUXes during system configuration, refer to the *Configuring Peripheral Pin Multiplexing* chapter.

26.3.5.1. Configuring Multiplexing at System Generation

There are 48 HPS peripheral pins that are shared with the FPGA core. They are divided into four quadrants of 12 signals per quadrant. Each quadrant can be configured with the Platform Designer system integration tool to be assigned to the HPS or the FPGA fabric.

The select for this multiplexer is in the I/O configuration shift registers (IOCSRs) which are configured by the Intel Quartus Prime I/O programming file.

When you configure the HPS component, Platform Designer determines the correct register settings, and creates a device tree for the boot loader. When the system boots up, the boot loader configures the registers before configuring the I/O chain.

26.3.5.2. Configuring Multiplexing at Boot Time

Typically, the boot code programs the `configuration_dedicated_io_bank` register when the system boots up. The boot code reads the BOOTSEL0, BOOTSEL1, and BOOTSEL2 pins and then sets the dedicated I/O bank to either 1.8 V or 2.5-3.0 V operation, depending on the pin status.

26.4. Test Considerations

The dedicated I/O pins are chained into the full chip JTAG boundary scan chain. However, in some power modes the HPS can be off or disabled. The SoC device provides a bypass MUX to remove the dedicated I/O pins from the scan chain in this situation.

The boundary scan phase is not required to include I/O configuration shift register (IOCSR) configuration for the CONFIG_IO instruction. The only requirement is that no software be executing on the HPS during boundary scan.

If CONFIG_IO mode is active during the boundary scan phase, the HPS is in cold reset, preventing any software interference with the boundary scan. However, if the I/Os are configured in user mode, CONFIG_IO mode is not active during the scan phase, and you must implement safeguards to prevent software from executing during scan.

For information about JTAG boundary-scan testing in Arria 10 devices, refer to "JTAG Boundary-Scan Testing" in the *Arria 10 Devices* chapter of the *Arria 10 Core Fabric and General Purpose I/O Handbook*.

26.5. I/O Pin MUX Address Map and Register Definitions for Arria 10

For complete HPS address map and register definitions, refer to the [Arria 10 HPS Address Map and Register Definitions](#).

26.5.1. io48_pin_mux_shared_3v_io_grp Address Map

This set of registers is used to configure the 48 I/O that are shared between the HPS and the FPGA. These I/O are 3.0 V.

Module Instance	Base Address	End Address
i_io48_pin_mux_shared_3v_io_grp	0xFFD07000	0xFFD071FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

26.5.1.2. pinmux_shared_io_q1_1

This register is used to control the peripherals connected to shared IO48 pin Q1 1
Only reset by a cold reset (ignores warm reset).
NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

Module Instance	Base Address	Register Address
i_io48_pin_mux_shared_3v_io_grp	0xFFD07000	0xFFD07000

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

26.5.1.49. pinmux_shared_io_q4_12

This register is used to control the peripherals connected to shared IO48 pin Q4 12
Only reset by a cold reset (ignores warm reset).
NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

26.5.2. io48_pin_mux_dedicated_io_grp Address Map

This set of registers is used to configure the dedicated 1.8 V and 3.0 V HPS I/O pins used for clock, reset, and external flash devices. Only 17 I/O are implemented as dedicated pins.

Module Instance	Base Address	End Address
i_io48_pin_mux_dedicated_io_grp	0xFFD07200	0xFFD073FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

13	PU_SLW_RT	Configuration bit for output pull up slew rate control 0 : slow P slew 1 : fast P slew	RW	0x0
12:8	PU_DRV_STRG	Configuration bits for PMOS pull up drive strength Pending Characterization	RW	0x0

continued...

Bit	Name	Description	Access	Reset
7:6	Reserved_7to6	Reserved	RO	0x0
5	PD_SLW_RT	Configuration bit for output pull down slew rate control 0 : slow N slew 1 : fast N slew	RW	0x0
4:0	PD_DRV_STRG	Configuration bits for NMOS pull down drive strength. Pending Characterization	RW	0x8

26.5.3. io48_pin_mux_fpga_interface_grp Address Map

This register set is used to select whether peripheral signals are mapped to the HPS or FPGA pins. This selection is available for the EMACs, I2Cs, NAND, QSPI, SD/MMC, SPIs and UARTs.

Module Instance	Base Address	End Address
i_io48_pin_mux_fpga_interface_grp	0xFFD07400	0xFFD10FFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description

26.5.3.2. pinmux_emac0_usefpga

Selection between HPS Pin and FPGA Interface for EMAC0 signals
Only reset by a cold reset (ignores warm reset).
NOTE: These registers should not be modified after IO configuration. There is no support for dynamically changing the Pin Mux selections.

Module Instance	Base Address	Register Address
i_io48_pin_mux_fpga_interface_grp	0xFFD07400	0xFFD07400

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

27. Introduction to the HPS Component

The hard processor system (HPS) component is a wrapper that interfaces logic in the user design to the HPS hard logic, simulation models, BFM, and software handoff files. It instantiates the HPS hard logic in the user design; and enables other soft components to interface with the HPS hard logic. The HPS component itself has a small footprint in the FPGA fabric, because its only purpose is to enable soft logic to connect to the extensive hard logic in the HPS. You can connect soft logic to the HPS.

After the soft logic is connected to the HPS, Platform Designer ensures the following features:

- Interoperability by adapting Avalon® Memory-Mapped (Avalon-MM) interfaces to AXI
- Handle data width mismatches
- Clock domain transfer crossing

This allows you to integrate IP from Intel, 3rd party IP cores, and custom IP cores to the HPS without having to create integration logic.

For a description of the HPS and its integration into the system on a chip (SoC), refer to the *Intel Intel Arria 10 Device Datasheet*.

For a description of the HPS system architecture and features, refer to the "Introduction to the Hard Processor" and the CoreSight Debug and Trace chapters in the *Intel Intel Arria 10 Device Datasheet*.

For more information about instantiating the HPS component, refer to the *Instantiating the HPS Component* chapter in the *Hard Processor System Technical Reference Manual*.

For more information about the HPS component interfaces, refer to the *HPS Component Interfaces* chapter in the *Hard Processor System Technical Reference Manual*.

For more information about simulating the HPS component, refer to the *Simulating the HPS Component* chapter in the *Hard Processor System Technical Reference Manual*.

27.1. MPU Subsystem

The MPU subsystem features the dual Arm Cortex-A9 MPCore processors.

Related Information

[Cortex-A9 Microprocessor Unit Subsystem](#) on page 1022

27.2. Arm CoreSight Debug Components

The following lists the Arm CoreSight debug components:

- Debug Access Port (DAP)
- System Trace Macrocell (STM)
- Trace Funnel
- Embedded Trace FIFO (ETF)
- AMBA Trace Bus Replicator (Replicator)
- Embedded Trace Router (ETR)
- Trace Port Interface Unit (TPIU)
- Embedded Cross Trigger (ECT)
- Program Trace Macrocell (PTM)

Related Information

[CoreSight Debug and Trace](#) on page 1064

27.3. Interconnect

The interconnect consists of the L3 interconnect, SDRAM L3 interconnect, and level 4 (L4) buses. The L3 interconnect is an network-on-chip (NOC) interconnect module.

Related Information

[System Interconnect](#) on page 364

27.4. HPS-to-FPGA Interfaces

The HPS-to-FPGA interfaces provide a variety of communication channels between the HPS and the FPGA fabric. The HPS is highly integrated with the FPGA fabric, resulting in thousands of connecting signals. Some of the HPS-to-FPGA interfaces include:

- FPGA-to-HPS port
- HPS-to-FPGA port
- Lightweight HPS-to-FPGA port
- FPGA-to-SDRAM interface

Related Information

[HPS-FPGA Bridges](#) on page 1007

27.5. Memory Controllers

The following lists the memory controller peripherals:

- SDRAM L3 Interconnect
- NAND Flash Controller
- Quad SPI Controller
- SD/MMC Controller

Related Information

- [System Interconnect](#) on page 364
- [NAND Flash Controller](#) on page 1456
- [SD/MMC Controller](#) on page 1685
- [Quad SPI Flash Controller](#) on page 1874

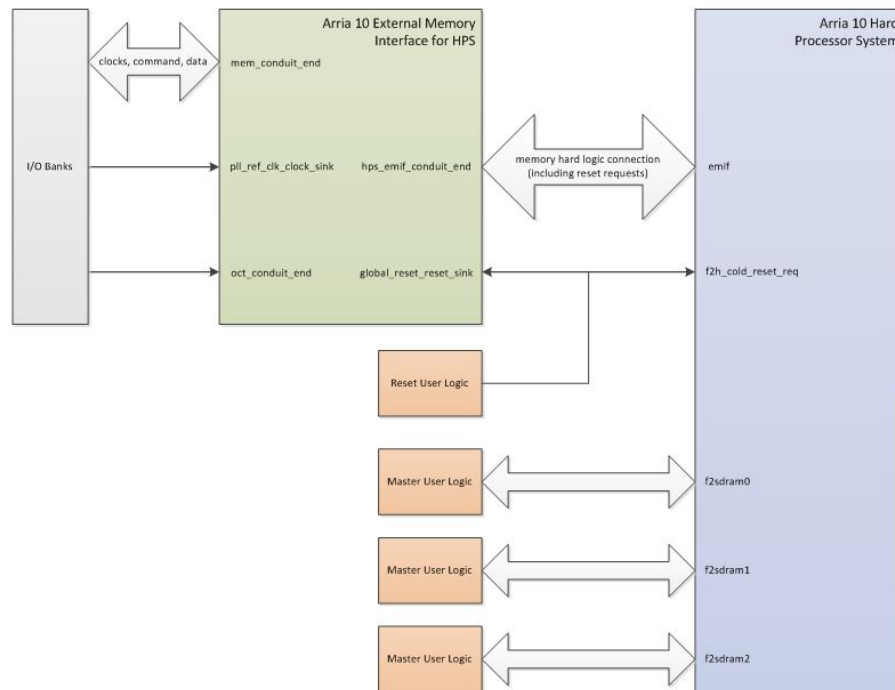

27.5.1. HPS SDRAM Controller

There are several memory interfaces connected, but only one connection to each interface is allowed at one time. You must instantiate a separate SDRAM controller and connect it to the HPS.

27.5.1.1. HMC and HPS Connectivity

The following figure shows that the HMC clock comes from the I/O itself, the HPS can reset the memory through the dedicated hard-logic connection between them, and any logic in the FPGA that resets the HMC must also be connected to the HPS.

Figure 190. HMC and HPS Connectivity

27.5.1.2. Clocks

You must connect the SDRAM controller to a reference clock that comes from the I/O column where the RAM controller is located.

27.5.1.3. Resets

There are two ways that the SDRAM controller can be connected to reset.

- One way - Reset and status connection is automatic by just connecting the SDRAM Hard Memory Controller (HMC) to the HPS. You access these wires in the reset manager so that you can reset the HMC and find out when the reset is complete.
- Second way - The HMC reset input from the FPGA fabric. This signal is called `global_reset_n` and is one of the signals exposed to the FPGA fabric from the HMC when you instantiate it in Platform Designer. The purpose of this signal is to reset the HMC from the FPGA side of the fabric. Before the FPGA fabric is configured, the memory controller ignores this signal which is why the memory controller can become live before the fabric is configured. This also means that the user design that gets configured into the fabric must drive it because once the fabric is configured, the HMC will use `global_reset_n` as an input source.

Note:

You must connect the input source for `global_reset_n` to the cold reset input for the HPS. If you put the SDRAM into reset but that same reset source does not connect to the HPS, the memory is then wiped out while the HPS is still trying to access it. This causes the software to crash.

28.1. Using the HPS Parameter Editor

1. Install the Arria 10 ACDS version 17.0.
2. Open the Quartus Prime software.
3. Open Platform Designer by selecting **Tools ► Platform Designer**.
4. In the **Device Family** tab, select a 10ASxxx device from the **Device** pull-down menu.
5. In the **IP Catalog** tab, under Library, select **Processors and Peripherals ► Hard Processor Systems ► Arria 10 Hard Processor System**.

Figure 191. Platform Designer Device Family Tab

28.2. FPGA Interfaces

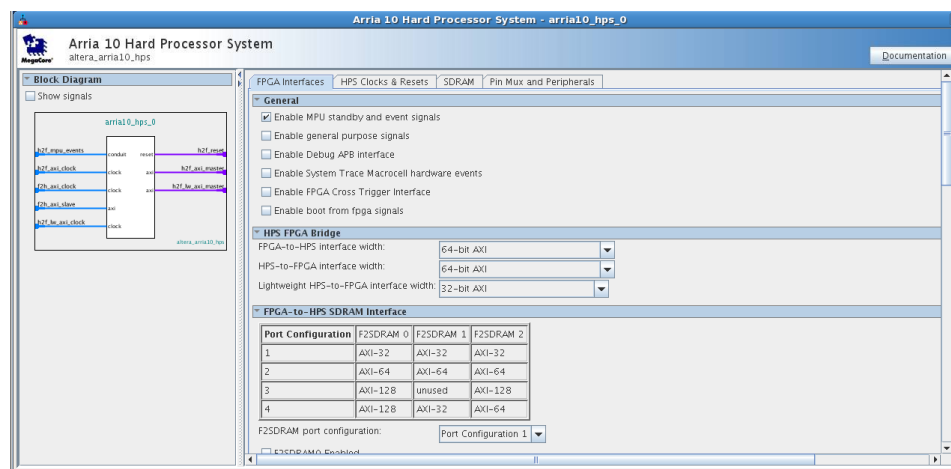

The **FPGA Interfaces** tab is one of four tabs on the HPS Component. This tab contains several groups with the parameters shown in the following figure.

28.2.1. General Interfaces

When enabled, the interfaces described in the following table become visible in the HPS component.

Table 257. General Parameters

Parameter Name	Parameter Description	Interface Name
Enable MPU standby and event signals	Enables interfaces that perform the following functions: <ul style="list-style-type: none"> Notify the FPGA fabric that the microprocessor unit (MPU) is in standby mode. Wake up an MPCore processor from a wait for event (WFE) state. 	h2f_mpu_events
	Input for FPGA to signal events to both processors. This signal must be asserted high for at least two MPU clock cycles to be visible to either Cortex-A9 processor core. This signal is used to wake either processor core from standby mode.	h2f_mpu_eventi
	Output event from either processor sent to the FPGA. The output event is a multiple cycle pulse so logic in the FPGA should detect it using a rising edge detector circuit to detect the occurrence of the event. This signal is asserted each time either processor executes the SEV instruction.	h2f_mpu_evento
	Output per processor that indicates if the processor is in WFE standby mode. When high the processor is in WFE standby mode.	h2f_mpu_standbywfe [1..0]
	Output per processor that indicates if the processor is in WFI standby mode. When high the processor is in WFI standby mode.	h2f_mpu_standbywfi [1..0]
<i>continued...</i>		

Parameter Name	Parameter Description	Interface Name
Enable general purpose signals	Enables a pair of 32-bit unidirectional general-purpose interfaces between the FPGA fabric and the FPGA manager in the HPS portion of the SoC device.	h2f_gp <ul style="list-style-type: none"> h2f_gp_in [31..0] h2f_gp_out [31..0]
Enable Debug APB interface	Enables debug interface to the FPGA, allowing access to debug components in the HPS. For more information, refer to the <i>CoreSight Debug and Trace</i> chapter.	h2f_debug_apb <ul style="list-style-type: none"> h2f_dbg_apb_PADDR [17..0] h2f_dbg_apb_PADDR31 h2f_dbg_apb_PENABLE h2f_dbg_apb_PRDATA [31..0] h2f_dbg_apb_PREADY h2f_dbg_apb_PSEL h2f_dbg_apb_PSLVERB h2f_dbg_apb_PWDATA [31..0] h2f_dbg_apb_PWRITE h2f_debug_apb_sideband <ul style="list-style-type: none"> h2f_debug_apb_PCLKEN h2f_debug_apb_DBG_APB_DISSABLE h2f_debug_apb_clock <ul style="list-style-type: none"> h2f_dbg_apb_clk h2f_debug_apb_reset <ul style="list-style-type: none"> h2f_dbg_apb_rst_n
Enable System Trace Macrocell hardware events	Enables system trace macrocell (STM) hardware events, allowing logic inside the FPGA to insert messages into the trace stream. For more information, refer to the <i>CoreSight Debug and Trace</i> chapter.	f2h_stm_hw_events <ul style="list-style-type: none"> f2h_stm_hwevents [27..0]
Enable FPGA Cross Trigger interface	Enables the cross trigger interface (CTI), which allows trigger sources and sinks to interface with the embedded cross trigger (ECT). For more information, refer to the <i>CoreSight Debug and Trace</i> chapter. If this interface has to be connected to a SignalTap II instance in the FPGA fabric, then it has to be left disabled in Platform Designer.	h2f_cti <ul style="list-style-type: none"> h2f_cti_trig_in [7..0] h2f_cti_trig_out_ack [7..0] h2f_cti_trig_out [7..0] h2f_cti_trig_in_ack [7..0]
Enable boot from FPGA signals	Enables an input to the HPS indicating whether a preloader is available in the on-chip memory of the FPGA. This option also enables a separate input to the HPS indicating a fallback preloader is available in the FPGA memory. A fallback preloader is used when there is no valid preloader image found in flash memory. For more information, refer to <i>Appendix A: Booting and Configuration</i> .	f2h_boot_from_fpga
	This is an active high signal which the Boot ROM polls to determine when the FPGA is configured and the memory located at offset 0x0 from the FPGA to HPS bridge is ready to be written to. When the FPGA is not configured the hardware will drive this signal low. You will need to drive this signal high when the memory in the FPGA is ready to accept memory mapped transactions.	f2h_boot_from_fpga_ready

continued...

Parameter Name	Parameter Description	Interface Name
	<p>The f2h_boot_from_fpga_ready signal is used by the Boot ROM when accessing the public key stored in the FPGA. The Boot ROM will only use the signal if asserted to boot with the public key.</p> <p>For more information, refer to <i>Appendix A: Booting and Configuration</i>.</p>	
	<p>This is an active high signal which the Boot ROM polls when all the preloaders fail to load. This signal is driven low when the FPGA is not configured. You will need to drive the signal high in your design. The Boot ROM will continuously poll both f2h_boot_from_fpga signals until both are set.</p> <p>For more information, refer to <i>Appendix A: Booting and Configuration</i>.</p>	f2h_boot_from_fpga_on_failure

28.2.2. FPGA-to-HPS SDRAM Interface

In the FPGA-to-HPS SDRAM interface table, use the F2SDRAM port configuration pull-down menu to choose bus widths for each SDRAM. You can add one to three SDRAM ports that make the HPS SDRAM subsystem accessible to the FPGA fabric.

The following table shows the width options for the SDRAM ports in Platform Designer.

Table 258. FPGA-to-HPS SDRAM Port and Interface Names

Port configuration	F2SDRAM 0	F2SDRAM 1	F2SDRAM 2
1	AXI-32	AXI-32	AXI-32
2	AXI-64	AXI-64	AXI-64
3	AXI-128	unused	AXI-128
4	AXI-128	AXI-32	AXI-64

Table 259. FPGA-to-HPS SDRAM Port and Interface Names

Port Name	Interface Name
F2SDRAM 0	f2sdram0_data f2sdram0_clock
F2SDRAM 1	f2sdram1_data f2sdram1_clock
F2SDRAM 2	f2sdram2_data f2sdram2_clock

Note: You can configure the slave interface to a data width of 32-, 64-, 128-bits. To facilitate accessing this slave from a memory-mapped master with a smaller address width, you can use the *Intel Address Span Extender*.

Related Information

Using the [Address Span Extender Component](#) on page 4592
Address span extender details

28.2.3. DMA Peripheral Request

You can enable each direct memory access (DMA) controller peripheral request ID individually. Each request ID enables an interface for FPGA soft logic to request one of eight logical DMA channels to the FPGA.

Related Information

[DMA Controller](#) on page 1969
For more information, refer to the *DMA Controller* chapter in the *Intel Arria 10 Hard Processor System Technical Reference Manual*.

28.2.4. Security Manager

Table 260. Anti Tamper signals

Interface Name	Description	Associated Signal
h2f_security	The security manager anti-tamper interface provides communication between the anti-tamper logic in the FPGA and the HPS security manager.	f2h_security_anti_tamper_in f2h_security_anti_tamper_out

Related Information

28.2.5. Interrupts

Table 261. FPGA-to-HPS Interrupts Interface

Parameter Name	Parameter Description	Interface Name
Enable FPGA-to-HPS Interrupts	Enables interface for FPGA interrupt signals to the MPU (in the HPS).	f2h_irq0 f2h_irq1

You can enable the interfaces for each HPS peripheral interrupt to the FPGA.

Table 262. HPS-to-FPGA Interrupts Interface

The following table lists the available HPS to FPGA interrupt interfaces and the corresponding parameters to enable them.

Parameter Name	Parameter Description	Interface Name
Enable Clock Peripheral Interrupts	Enables interface for HPS clock manager and MPU wake-up interrupt signals to the FPGA	h2f_clkmgr_interrupt h2f_mpuwakeupt_interrupt
Enable CTI Interrupts	Enables interface for HPS cross-trigger interrupt signals to the FPGA	h2f_ncti_interrupt0 h2f_ncti_interrupt1
continued...		

Parameter Name	Parameter Description	Interface Name
Enable DMA Interrupts	Enables interface for HPS DMA channels interrupt and DMA abort interrupt to the FPGA	h2f_dma_interrupt0 h2f_dma_interrupt1 h2f_dma_interrupt2 h2f_dma_interrupt3 h2f_dma_interrupt4 h2f_dma_interrupt5 h2f_dma_interrupt6 h2f_dma_interrupt7 h2f_dma_abort_interrupt
Enable EMAC Interrupts	Enables interface for HPS Ethernet MAC controller interrupt to the FPGA. EMAC must be enabled in Pin Mux Tab before enabling interrupt.	h2f_emac0_interrupt h2f_emac1_interrupt h2f_emac2_interrupt
Enable FPGA manager Interrupts	Enables interface for the HPS FPGA manager interrupt to the FPGA	h2f_fpga_man_interrupt
Enable GPIO Interrupts	Enables interface for the HPS general purpose IO (GPIO) interrupt to the FPGA	h2f_gpio0_interrupt h2f_gpio1_interrupt h2f_gpio2_interrupt
Enable HMC Interrupts	Enable the HPS peripheral interrupt for HMC to be driven into the FPGA fabric.	h2f_hmc_interrupt
Enable I2C-EMAC Interrupts	Enable the HPS peripheral interrupt for I2CEMAC to be driven into the FPGA fabric	h2f_i2c_emac0_interrupt h2f_i2c_emac1_interrupt h2f_i2c_emac2_interrupt
Enable I2C Peripherals Interrupts	Enable the HPS peripheral interrupt for I2C0 to be driven into the FPGA fabric. The I2C must be enabled in the Pin Mux Tab before enabling interrupt.	h2f_i2c0_interrupt h2f_i2c1_interrupt
Enable L4 Timer Interrupts	Enables the HPS peripheral interrupt for L4TIMER to be driven into the FPGA fabric.	h2f_timer_l4sp_0_interrupt h2f_timer_l4sp_1_interrupt
Enable NAND Interrupts	Enables interface for the HPS NAND controller interrupt to the FPGA. The NAND IP Block must be enabled in Pin Mux Tab before enabling interrupt.	h2f_nand_interrupt
Enable Quad SPI Interrupts	Enables interface for the HPS QSPI controller interrupt to the FPGA. The Quad SPI IP Block must be enabled in Pin Mux Tab before enabling interrupt.	h2f_qspi_interrupt
Enable SYS Timer Interrupts	Enables the HPS peripheral interrupt for SYSTIMER to be driven into the FPGA fabric.	h2f_timer_sys_0_interrupt h2f_timer_sys_1_interrupt
Enable SD/MMC Interrupts	Enables interface for the HPS SD/MMC controller interrupt to the FPGA. The SD/MMC IP Block must be enabled in Pin Mux Tab before enabling interrupt.	h2f_sdmmc_interrupt
Enable SPI Master Interrupts	Enables interface for the HPS SPI master controller interrupt to the FPGA. The SPI Master IP Block must be enabled in Pin Mux Tab before enabling interrupt.	h2f_spim0_interrupt h2f_spim1_interrupt
continued...		

Parameter Name	Parameter Description	Interface Name
Enable SPI Slave Interrupts	Enables interface for the HPS SPI slave controller interrupt to the FPGA. The SPI IP Block must be enabled in Pin Mux Tab before enabling interrupt.	h2f_spis0_interrupt h2f_spis1_interrupt
Enable ECC/Parity_L1 Interrupts	Enables the HPS peripheral interrupt for ECC single and double bit error and L1 parity error to be driven into the FPGA fabric.	h2f_ecc_serr_interrupt h2f_ecc_derr_interrupt h2f_parity_l1_interrupt
Enable UART Interrupts	Enables interface for the HPS UART controller interrupt to the FPGA. The UART IP Block must be enabled in Pin Mux Tab before enabling interrupt.	h2f_uart0_interrupt h2f_uart1_interrupt
Enable USB Interrupts	Enables interface for the HPS USB controller interrupt to the FPGA. The USB IP Block must be enabled in Pin Mux Tab before enabling interrupt.	h2f_usb0_interrupt s2f_usb1_interrupt
Enable Watchdog Interrupts	Enables interface for the HPS watchdog interrupt to the FPGA	h2f_wdog0_interrupt h2f_wdog1_interrupt

28.2.6. AXI Bridges

Table 263. Bridge Parameters

Parameter Name	Parameter Description	Interface Name
FPGA-to-HPS interface width	Enable or disable the FPGA-to-HPS interface; if enabled, set the data width to 32, 64, or 128 bits.	f2h_axi_slave f2h_axi_clock
HPS-to-FPGA interface width	Enable or disable the HPS-to-FPGA interface; if enabled, set the data width to 32, 64, or 128 bits.	h2f_axi_master h2f_axi_clock
Lightweight HPS-to-FPGA interface width	Enable or disable the lightweight HPS-to-FPGA interface. When enabled, the data width is 32 bits.	h2f_lw_axi_master h2f_lw_axi_clock

Note: To facilitate accessing these slaves from a memory-mapped master with a smaller address width, you can use the Intel Platform Designer Address Span Extender.

28.3. Configuring HPS Clocks and Resets

The **HPS Clocks and Reset** tab is one of four tabs on the HPS Component. This tab contains several groups with the following parameters:

[Alternate Clock Source from FPGA](#) on page 4587

[User Clocks](#) on page 4587

[Reset Interfaces](#) on page 4587

[Peripheral FPGA Clocks](#) on page 4588

28.3.1. Alternate Clock Source from FPGA

Table 264. Alternate Clock Source Parameters

Parameter Name	Parameter Description	Clock Interface Name
Enable Alternate Clock Source from FPGA	Drives the HPS Clock source to originate from the FPGA fabric instead of the dedicated HPS input clock pin.	f2h_free_clk

28.3.2. User Clocks

When you enable a HPS-to-FPGA user clock, you must manually enter its maximum frequency for timing analysis. The TimeQuest Timing Analyzer has no other information about how software running on the HPS configures the phase-locked loop (PLL) outputs. Each possible clock, including clocks that are available from peripherals, has its own parameter for describing the clock frequency.

28.3.2.1. User Clock Parameters

The frequencies that you provide are the maximum expected frequencies. The actual clock frequencies can be modified through the register interface, for example by software running on the microprocessor unit (MPU). For further details, refer to *Selecting PLL Output Frequency and Phase*.

Parameter Name	Parameter Description	Clock Interface Name
Enable HPS-to-FPGA user 0 clock	Enable main PLL from HPS-to-FPGA	h2f_user0_clock
User 0 clock frequency	Specify the maximum expected frequency for the main PLL	
Enable HPS-to-FPGA user 1 clock	Enable peripheral PLL from HPS-to-FPGA	h2f_user1_clock
User 1 clock frequency	Specify the maximum expected frequency for the peripheral PLL	

28.3.2.2. Clock Frequency Usage

The clock frequencies you provide are reported in a Synopsys Design Constraints File (.sdc) generated by Platform Designer. The .sdc file will be referenced in the system .qip file when the system is generated.

Related Information

[Clock Manager](#) on page 56

For general information about clock signals, refer to the *Clock Manager* chapter in the *Intel Arria 10 Hard Processor System Technical Reference Manual*.

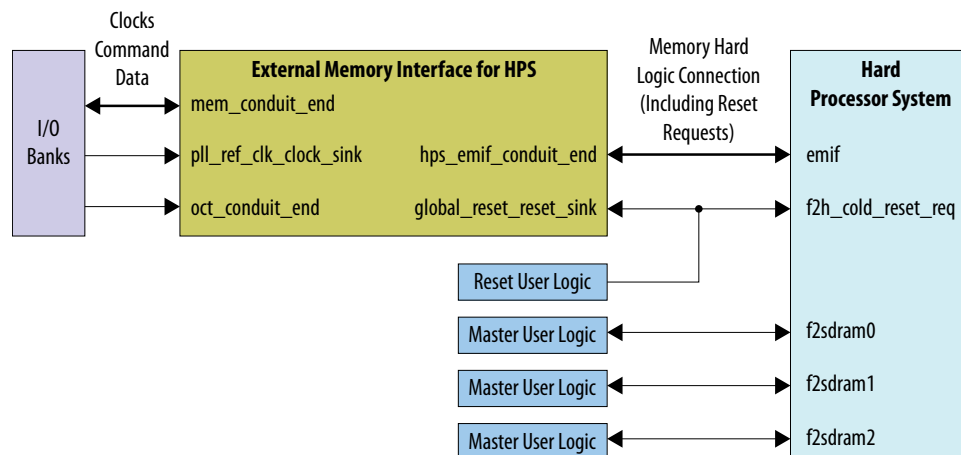

28.3.3. Reset Interfaces

You can enable the resets on an individual basis through the **HPS Clocks and resets** tab under the **Resets** sub tab.

Table 265. Reset Parameters

Parameter Name	Parameter Description	Interface Name
Enable HPS-to-FPGA cold reset output	Enable interface for HPS-to-FPGA cold reset output	h2f_cold_reset
Enable HPS warm reset handshake signals	Enable an additional pair of reset handshake signals allowing soft logic to notify the HPS when it is safe to initiate a warm reset in the FPGA fabric.	h2f_warm_reset_handshake
Enable FPGA-to-HPS debug reset request	Enable interface for FPGA-to-HPS debug reset request	f2h_debug_reset_req
Enable FPGA-to-HPS warm reset request	Enable interface for FPGA-to-HPS warm reset request	f2h_warm_reset_req
Enable FPGA-to-HPS cold reset request	Enable interface for FPGA-to-HPS cold reset request	f2h_cold_reset_req

Figure 193. Recommended SDRAM Reset Connections

The SDRAM reset relies on the **f2h_cold_reset_req** to be enabled. The reset can be enabled through the Platform Designer **Resets** tab.

Note: SDRAM and the EMIF conduit can be enabled through the Platform Designer **FPGA Interface** and **SDRAM** tab.

Related Information

[Reset Manager](#) on page 138

For more information about the reset interfaces, refer to *Functional Description of the Reset Manager* in the *Reset Manager* chapter in the *Intel Arria 10 Hard Processor System Technical Reference Manual*.

28.3.4. Peripheral FPGA Clocks

Parameter Name	Parameter Description
EMAC 0 (emac0_md_clk clock frequency)	If EMAC 0 peripheral is routed to FPGA, use the input field to specify EMAC 0 MDIO clock frequency
EMAC 0 (emac0_gtx_clk clock frequency)	If EMAC 0 peripheral is routed to FPGA, use the input field to specify EMAC 0 transmit clock frequency
<i>continued...</i>	

Parameter Name	Parameter Description
EMAC 1 (emac1_md_clk clock frequency)	If EMAC 1 peripheral is routed to FPGA, use the input field to specify EMAC 1 MDIO clock frequency
EMAC 1 (emac1_gtx_clk clock frequency)	If EMAC 1 peripheral is routed to FPGA, use the input field to specify EMAC 1 transmit clock frequency
EMAC 2 (emac2_md_clk clock frequency)	If EMAC 2 peripheral is routed to FPGA, use the input field to specify EMAC 2 MDIO clock frequency
EMAC 2 (emac2_gtx_clk clock frequency)	If EMAC 2 peripheral is routed to FPGA, use the input field to specify EMAC 2 transmit clock frequency
QSPI (qspi_sclk_out clock frequency)	If QSPI peripheral is routed to FPGA, use the input field to specify QSPI serial clock frequency
SDMMC (sdmmc_cclk)	If this peripheral pin multiplexing is configured to route to FPGA fabric, use the input field to specify the SDMMC sdmmc_cclk clock frequency
SPIM 0 (spim0_sclk_out clock frequency)	If SPI master 0 peripheral is routed to FPGA, use the input field to specify SPI master 0 output clock frequency
SPIM 1 (spim1_sclk_out clock frequency)	If SPI master 1 peripheral is routed to FPGA, use the input field to specify SPI master 1 output clock frequency
I ² C0 (i2c0_clk clock frequency)	If I ² C 0 peripheral is routed to FPGA, use the input field to specify I ² C 0 output clock frequency
I ² C1 (i2c1_clk clock frequency)	If I ² C 1 peripheral is routed to FPGA, use the input field to specify I ² C 1 output clock frequency
I2CEMAC0 (i2cemac0_clk)	If this peripheral pin multiplexing is configured to route to the FPGA fabric, use the input field to specify the I2CEMAC0 i2cemac0_clk clock frequency
I2CEMAC1 (i2cemac1_clk)	If this peripheral pin multiplexing is configured to route to the FPGA fabric, use the input field to specify the I2CEMAC1 i2cemac1_clk clock frequency
I2CEMAC2 (i2cemac2_clk)	If this peripheral pin multiplexing is configured to route to the FPGA fabric, use the input field to specify the I2CEMAC2 i2cemac2_clk clock frequency

28.4. Configuring Peripheral Pin Multiplexing

The **Pin Mux and Peripherals** tab is one of four tabs on the HPS Component. This tab contains several groups with the following parameters:

[Configuring Peripherals](#) on page 4589

[Connecting Unassigned Pins to GPIO](#) on page 4591

[Peripheral Signals Routed to FPGA](#) on page 4591

28.4.1. Configuring Peripherals

The **Pin MUX and Peripherals** tab contains three sub tabs **IP Selection**, **Advanced Pin Placement**, and **Advanced FPGA Placement**. The **IP Selection** tab contains a list of peripherals that can be enabled and either routed to the HPS I/Os or to the FPGA. You can enable one or more instances of each peripheral type by using the drop down menu next to each peripheral. When enabled, some peripherals also have mode settings specific to their functions.

Note: Once you have selected a peripheral, you must click the **Apply Selections** button in order to enable the selected peripherals.

Under the the **IP Selection** tab, Platform Designer allows you to boot from the following flash device sources if selected.

- NAND
- SD/MMC
- QSPI

In the **Advanced Pin Placement** tab you can be more specific about the placement of each peripheral in the HPS dedicated I/O and HPS shared I/O quadrant space. Each location has a pull down IP selection menu where you can select a peripheral for the location.

Pin placement for peripherals cannot span both dedicated I/O and HPS shared I/O, except for the following situations:

- QSPI signals `qspi_ss_o[2]` and `qspi_ss_o[3]` are available to the HPS shared I/O and can be routed to any quadrant selected.
- If the SD/MMC signals are routed to the HPS shared I/O, and the `SDMMC_PWR_ENA` pin is required, then it is only available to the HPS dedicated I/O.
- If the signals for all three EMACs are routed to the HPS shared I/O, the MDIO signals for all three EMACs can be routed to the HPS dedicated I/Os.
- If the NAND Flash Controller pins are routed to the HPS dedicated I/O, `NAND_WP_N` is only available to the HPS shared I/O.

In addition, peripheral pins cannot span multiple quadrants within the HPS shared I/O. All pins of an instance must be self-contained in one quadrant, except for NANDx16 and the GPIO modules because of the number of pins required for these peripherals. For example, NANDx16 may be routed to either quadrant 1 and quadrant 2 or quadrant 3 and quadrant 4.

The **Advanced FPGA Placement** tab allows you to route peripherals to the FPGA. Aside from the **IP Selection** tab this tab allows you to focus on the FPGA routing only. There are also SDMMC and NAND Bit-width options. You can select the EMAC interface and PHY options on this tab if peripheral is selected.

Note: Changes in the **IP Selection** tab carry over to the **Advanced Pin Placement** tab, **Advanced FPGA Placement** tab, and vice versa.

You can enable the following types of peripherals:

- [I2C Controller](#) on page 4093
- [UART Controller](#) on page 4267

28.4.1.1. Boot Source

Under the **IP Selection** tab you have the option to choose a nonvolatile flash-based memory to be the boot source. The following flash controller peripherals under the IP block list in the **IP Selection** tab have a **Boot** enable button beside them where you can make this selection.

- NAND
- SD/MMC
- QSPI

Related Information

[Boot and Configuration](#) on page 4634

For detailed information about the HPS boot sequence, refer to the *Boot and Configuration*.

28.4.2. Connecting Unassigned Pins to GPIO

For pins that are not assigned to any peripherals, you can assign them to the GPIO peripheral by clicking on the corresponding GPIO push button in the table. Click on the selected push button to remove GPIO pin assignment. The table also shows the GPIO bit number that correlates to the I/O pins.

28.4.3. Peripheral Signals Routed to FPGA

You can route the peripheral signals to the FPGA fabric and assign them to the FPGA I/O pins.

The following steps show you how to enable the peripheral signals:

1. Select a peripheral in the IP Selection list.
2. Choose the To FPGA drop-down box next to the IP you have selected and choose the amount of instances for the peripheral
3. Click the Apply Selections button at the bottom of the peripherals list.

28.5. Configuring the External Memory Interface

The **SDRAM** tab is one of four tabs on the HPS component. Enable the conduit to connect to the Arria 10 External Memory Interface. This option enables a conduit interface for the HPS to talk to the Arria 10 External Memory interfaces for the HPS.

The HPS supports one memory interface implementing double data rate 3 (DDR3), double data rate 3 Low Voltage (DDR3L), and double data rate 4 (DDR4) protocols.

Related Information

External Memory Interface In Arria 10 Devices

For more information on the A10 External Memory Interface, refer to the External Memory Interfaces in Arria 10 Devices in the Arria 10 Core Fabric and General Purpose I/O Handbook.

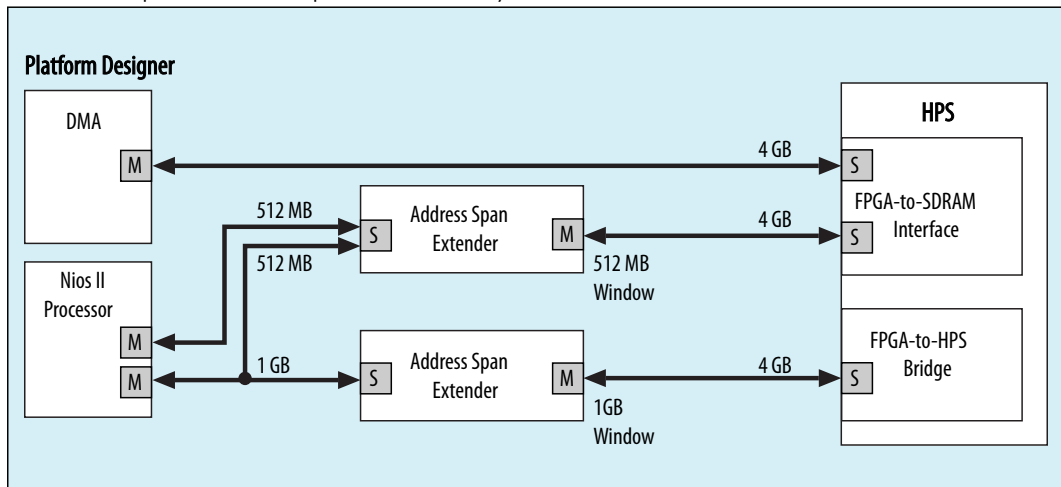

28.6. Using the Address Span Extender Component

The FPGA-to-HPS bridge and FPGA-to-HPS SDRAM memory-mapped interfaces expose their entire 4-GB address spaces to the FPGA fabric. The address span extender component provides a memory-mapped window into the address space that it masters. Using the address span extender, you can expose portions of the HPS memory space without needing to expose the entire 4 GB address space.

You can use the address span extender between a soft logic master and an FPGA-to-HPS bridge or FPGA-to-HPS SDRAM interface. This component reduces the number of address bits required for a master to address a memory-mapped slave interface located in the HPS.

Figure 194. Address Span Extender Components

Two address span extender components used in a system with the HPS.

You can also use the address span extender in the HPS-to-FPGA direction, for slave interfaces in the FPGA. In this case, the HPS-to-FPGA bridge exposes a limited, variable address space in the FPGA, which can be paged in using the address span extender.

For example, suppose that the HPS-to-FPGA bridge has a 1-GB span, and the HPS needs to access three independent 1-GB memories in the FPGA portion of the device. To achieve this, the HPS programs the address span extender to access one SDRAM (1-GB) in the FPGA at a time. This technique is commonly called paging or windowing.

Related Information

[Platform Designer User Guide: Intel Quartus Prime Pro Edition](#)

For more information about the Span Extender, refer to the Address Span Extender section in the *Platform Designer User Guide: Intel Quartus Prime Pro Edition*.

28.7. Generating and Compiling the HPS Component

The process of generating and compiling an HPS design is very similar to the process for any other Platform Designer project. Perform the following steps:

1. Generate the design with Platform Designer. The generated files include an **.sdc** file containing clock timing constraints. If simulation is enabled, simulation files are also generated.
2. Add `<qsys_system_name>.qip` to the Quartus Prime project.
`<qsys_system_name>.qip` is the Quartus Prime IP File for the HPS component, generated by Platform Designer.
Note: Platform Designer generates pin assignments in the **qip** file.
3. Perform analysis and synthesis with the Quartus Prime software.
4. Compile the design with the Quartus Prime software.
5. Optionally back-annotate the SDRAM pin assignments, to eliminate pin assignment warnings the next time you compile the design.

Related Information

- [Configuring Peripheral Pin Multiplexing](#) on page 4589

For a description of the simulation files generated, refer to "Simulation Flow" in the Simulating the HPS Component chapter of the *Intel Arria 10 Hard Processor System Technical Reference Manual*.

29. HPS Component Interfaces

This chapter describes the interfaces, including clocks and resets, implemented by the hard processor system (HPS) component.

The majority of the resets can be enabled on an individual basis. The exception is the `h2f_reset` interface, which is always enabled.

You must declare the clock frequency of each HPS-to-FPGA clock for timing purposes. Each possible clock, including ones that are available from peripherals, has its own parameter for describing the clock frequency. Declaring the clock frequency for HPS-to-FPGA clocks specifies how you plan to configure the PLLs and peripherals, to enable TimeQuest to accurately estimate system timing. It has no effect on PLL settings.

29.1. Memory-Mapped Interfaces

29.1.1. FPGA-to-HPS Bridge

Interface Name	Description	Associated Clock Interface
<code>f2h_axi_slave</code>	FPGA-to-HPS AXI slave interface	<code>f2h_axi_clock</code>

The FPGA-to-HPS interface is a configurable data width AXI slave allowing FPGA masters to issue transactions to the HPS. This interface allows the FPGA fabric to access the majority of the HPS slaves. This interface also provides a coherent memory interface.

Other interface standards in the FPGA fabric, such as connecting to Avalon® Memory-Mapped (Avalon-MM) interfaces, can be supported through the use of soft logic adapters. The Platform Designer system integration tool automatically generates adapter logic to connect AXI to Avalon-MM interfaces.

The FPGA-to-HPS interface is an AXI-3 compliant interface with the following features:

- Configurable data width: 32, 64, or 128 bits
- Ready latency support data widths: 32, 64, or 128 bits

Related Information

- [Clocks](#) on page 4597

29.1.2. HPS-to-FPGA and Lightweight HPS-to-FPGA Bridges

Table 266. HPS-to-FPGA and Lightweight HPS-to-FPGA Bridges and Clocks

Interface Name	Description	Associated Clock Interface
h2f_axi_master	HPS-to-FPGA AXI master interface	h2f_axi_clock
h2f_lw_axi_master	HPS-to-FPGA lightweight AXI master interface	h2f_lw_axi_clock

The HPS-to-FPGA interface is a configurable data width AXI master (32-, 64-, or 128-bit) that allows HPS masters to issue transactions to the FPGA fabric.

The lightweight HPS-to-FPGA interface is a 32-bit AXI master that allows HPS masters to issue transactions to the FPGA fabric.

Other interface standards in the FPGA fabric, such as connecting to Avalon-MM interfaces, can be supported through the use of soft logic adaptors. The Platform Designer system integration tool automatically generates adaptor logic to connect AXI to Avalon-MM interfaces.

Each AXI bridge accepts a clock input from the FPGA fabric and performs clock domain crossing internally. The exposed AXI interface operates on the same clock domain as the clock supplied by the FPGA fabric.

Latency Support for (32-,64, or 128-bit)

29.1.3. FPGA-to-HPS SDRAM Interface

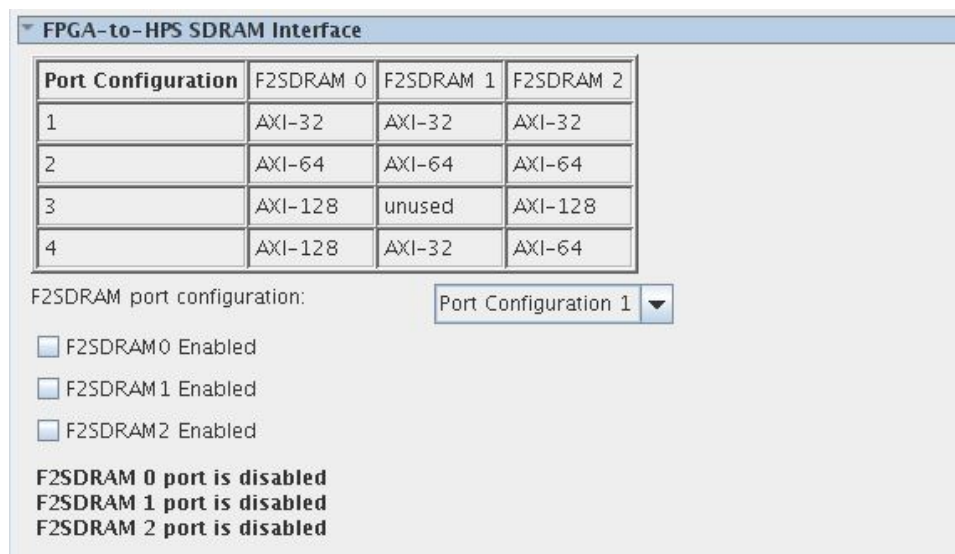

The FPGA-to-HPS SDRAM interface is a direct connection between the FPGA fabric and the HPS SDRAM controller. The interface is highly configurable, allowing a mix between the four port configurations and the port width. The FPGA-to-HPS SDRAM interface supports AMBA AXI interface standards.

Table 267. FPGA-to-HPS SDRAM Interfaces and Clocks

Interface Name	Associated Data Interface	Associated Clock Interface
F2SDRAM0	f2sdram0_data	f2sdram0_clock
F2SDRAM1	f2sdram1_data	f2sdram1_clock
F2SDRAM2	f2sdram2_data	f2sdram2_clock

The FPGA-to-HPS SDRAM interface is a configurable interface to the multi-port SDRAM controller. There are four port configurations that are a combination of the SDRAM ports 0 - 2 that you are able to select. Once a port configuration is selected, you can choose to enable the ports that you need.

The total data width of all interfaces is limited to a maximum of 256 bits in the read direction and 256 bits in the write direction. The HPS SDRAM controller supports up to 3 masters (command ports), 3x 64-bit read data ports and 3x 64-bit write data ports.

Figure 195. FPGA-to-HPS SDRAM Platform Designer Interface

Port Configuration	F2SDRAM 0	F2SDRAM 1	F2SDRAM 2
1	AXI-32	AXI-32	AXI-32
2	AXI-64	AXI-64	AXI-64
3	AXI-128	unused	AXI-128
4	AXI-128	AXI-32	AXI-64

F2SDRAM port configuration: Port Configuration 1 ▼

☐ F2SDRAM0 Enabled

☐ F2SDRAM1 Enabled

☐ F2SDRAM2 Enabled

F2SDRAM 0 port is disabled
F2SDRAM 1 port is disabled
F2SDRAM 2 port is disabled

Related Information

- [Clocks](#) on page 4597
- [HPS Component Interfaces](#) on page 4594
For information about the address span extender, refer to "Using the Address Span Extender Component" in the *Instantiating the HPS Component* chapter.

29.1.4. EMIF Conduit

Under the SDRAM tab in Platform Designer, the EMIF conduit can be enabled. This enables the HPS dedicated conduit to the Arria 10 External Interface for the HPS. This conduit cannot connect to any other External Memory Interface (EMIF). Only IP generated by the Arria 10 External Memory Interface for HPS Platform Designer library should be used.

29.2. Clocks

The HPS-to-FPGA clock interface supplies physical clocks to the FPGA. These clocks and resets are generated in the HPS.

29.2.1. Alternative Clock Inputs to HPS PLLs

This section lists alternative clock inputs to HPS PLLs.

- `f2h_free_clk`—FPGA-to-HPS free clock. Drives the HPS clock source to originate from the FPGA fabric instead of the dedicated HPS input clock pin.

29.2.2. User Clocks

A user clock is a PLL output that is connected to the FPGA fabric rather than the HPS. You can connect a user clock to logic that you instantiate in the FPGA fabric.

- `h2f_user0_clock`—HPS-to-FPGA user clock, driven from main PLL
- `h2f_user1_clock`—HPS-to-FPGA user clock, driven from peripheral PLL

29.2.3. AXI Bridge FPGA Interface Clocks

The AXI interface has an asynchronous clock crossing in the FPGA-to-HPS bridge. The FPGA-to-HPS and HPS-to-FPGA interfaces are synchronized to clocks generated in the FPGA fabric. These interfaces can be asynchronous to one another.

- `f2h_axi_clock`—AXI slave clock for FPGA-to-HPS bridge, generated in FPGA fabric
- `h2f_axi_clock`—AXI master clock for HPS-to-FPGA bridge, generated in FPGA fabric
- `h2f_lw_axi_clock`—AXI master clock for lightweight HPS-to-FPGA bridge, generated in FPGA fabric

29.2.4. SDRAM Clocks

You can configure the HPS component with up to three FPGA-to-HPS SDRAM clocks.

Each command channel to the SDRAM controller has an individual clock source from the FPGA fabric. The interface clock is always supplied by the FPGA fabric, with clock crossing occurring on the HPS side of the boundary.

The FPGA-to-HPS SDRAM clocks are driven by soft logic in the FPGA fabric.

- `f2h_sdram0_clock`—SDRAM clock for port 0
- `f2h_sdram1_clock`—SDRAM clock for port 1
- `f2h_sdram2_clock`—SDRAM clock for port 2

29.2.5. Peripheral FPGA Clocks

Table 268. Peripheral FPGA Clocks

Clock Name	Description
emac_md_clk	Ethernet PHY management interface clock
emac_gtx_clk	Ethernet transmit clock that is used by the PHY in GMII mode
emac_rx_clk_in	Ethernet MAC reference clock from the PHY
emac_tx_clk_in	Ethernet MAC uses this clock input for TX reference
emac_ptp_ref_clock	Ethernet timestamp precision time protocol (PTP) reference clock
qspi_sclk_out	QSPI master clock output
qspi_s2f_clk	QSPI serial clock output (connects to the FPGA clock network)
sdmmc_clk_in	Clock for SD/MMC controller
sdmmc_cclk	Generated output clock for card
spim_sclk_out	SPI master serial clock output
spis_sclk_in	SPI slave serial clock input
i2c_clk	I ² C outgoing clock (part of the SCL bidirectional pin signals)
i2c_scl_in	I ² C incoming clock (part of the SCL bidirectional pin signals)
i2cemac_clk	I ² C EMAC outgoing clock

Note: The Peripheral FPGA Clocks can only be accessed once the corresponding IP Block has been selected and routed to the FPGA through the Pin Mux and Peripherals tab.

29.3. Resets

This section describes the reset interfaces to the HPS component.

Related Information

[Reset Manager](#) on page 138

For details about the HPS reset sequences, refer to the *Functional Description of the Reset Manager* in the *Reset Manager* chapter .

29.3.1. HPS-to-FPGA Reset Interfaces

The following interfaces allow the HPS to reset soft logic in the FPGA fabric:

- h2f_reset—HPS-to-FPGA warm reset
- h2f_cold_reset—HPS-to-FPGA cold reset
- h2f_warm_reset_handshake—Warm reset request and acknowledge interface between HPS and FPGA

29.3.2. HPS External Reset Request

The following interfaces allow soft logic in the FPGA fabric to request for different types of HPS resets:

- `f2h_cold_reset_req`—FPGA-to-HPS cold reset request
- `f2h_warm_reset_req`—FPGA-to-HPS warm reset request
- `f2h_dbg_reset_req`—FPGA-to-HPS debug reset request

29.3.3. Peripheral Reset Interfaces

The following are Ethernet reset interfaces, that can be used when the Ethernet is routed to the FPGA:

- `emac_tx_reset`— Ethernet transmit clock reset output used to reset external PHY TX clock domain logic
- `emac_rx_reset`— Ethernet receive clock reset output used to reset external PHY RX clock domain logic

29.4. Debug and Trace Interfaces

29.4.1. FPGA System Trace Macrocell Events Interface

The system trace macrocell (STM) hardware events allow logic in the FPGA to insert messages into the trace stream.

- `f2h_stm_hw_events`

29.4.2. FPGA Cross Trigger Interface

The cross trigger interface (CTI) allows trigger sources and sinks to interface with the embedded cross trigger (ECT).

- `h2f_cti`

29.4.3. Debug APB Interface

The debug Advanced Peripheral Bus (APB) interface allows debug components in the FPGA fabric to debug components on the CoreSight debug APB.

- `h2f_debug_apb`
- `h2f_debug_apb_sideband`
- `h2f_debug_apb_reset`
- `h2f_debug_apb_clock`

29.5. Peripheral Signal Interfaces

29.5.1. Platform Designer Peripheral Port Interface Mapping

For many of the HPS component peripherals, the Platform Designer ports can be routed to the HPS pins, FPGA pins or both. The following tables show the available mappings.

29.5.1.1. NAND Flash Controller Interface

Table 269. NAND Flash Controller Interface Platform Designer Port Mappings

Platform Designer Port Name	Routed to FPGA	Routed to HPS I/O	HPS Pin Name
nand_adq_i[15:0]	Yes	Yes	NAND_ADQ[15:0]
nand_adq_oe	Yes	Yes	
nand_adq_o[15:0]	Yes	Yes	
nand_ale_o	Yes	Yes	NAND_ALE
nand_ce_o[3:0]	Yes, 4 chip enables	Yes, 1 chip enable	NAND_CE_N
nand_cle_o	Yes	Yes	NAND_CLE
nand_re_o	Yes	Yes	NAND_RE_N
nand_rdy_busy_i[3:0]	Yes, 4 ready/busy signals	Yes, 1 ready/busy signal	NAND_RB
nand_we_o	Yes	Yes	NAND_WE_N
nand_wp_o	Yes	Yes	NAND_WP_N

29.5.2. DMA Controller Interface

The DMA controller interface allows soft IP in the FPGA fabric to communicate with the DMA controller in the HPS. You can configure up to eight separate interface channels.

- f2h_dma0—FPGA DMA controller peripheral request interface 0
- f2h_dma1—FPGA DMA controller peripheral request interface 1
- f2h_dma2—FPGA DMA controller peripheral request interface 2
- f2h_dma3—FPGA DMA controller peripheral request interface 3
- f2h_dma4—FPGA DMA controller peripheral request interface 4
- f2h_dma5—FPGA DMA controller peripheral request interface 5
- f2h_dma6—FPGA DMA controller peripheral request interface 6
- f2h_dma7—FPGA DMA controller peripheral request interface 7

Each of the DMA peripheral request interface contains the following three signals:

- f2h_dma_req—This signal is used to request burst transfer using the DMA
- f2h_dma_single—This signal is used to request single word transfer using the DMA
- f2h_dma_ack—This signal indicates the DMA acknowledgment upon requests from the FPGA

Related Information

[DMA Controller](#) on page 1969

29.6. Other Interfaces

Related Information

[Cortex-A9 MPCore](#) on page 1025

For more information, refer to *Cortex-A9 MPU Subsystem* .

29.6.1. MPU Standby and Event Interfaces

MPU standby signals are notification signals to the FPGA fabric that the MPU is in standby. Event signals are used to wake up the Cortex-A9 processors from a wait for event (WFE) state. The following shows the signals in the interface:

- `h2f_mpu_eventi`—Sends an event from logic in the FPGA fabric to the MPU. This FPGA-to-HPS signal is used to wake up a processor that is in a Wait For Event state. Asserting this signal has the same effect as executing the SEV instruction in the Cortex-A9. This signal must be de-asserted until the FPGA fabric is powered-up and configured.
- `h2f_mpu_evento`—Sends an event from the MPU to logic in the FPGA fabric. This HPS-to-FPGA signal is asserted when an SEV instruction is executed by one of the Cortex-A9 processors.
- `h2f_mpu_standbywfe[1:0]`—Indicates which Cortex-A9 processor is in the WFE state
- `h2f_mpu_standbywfi[1:0]`—Indicates which Cortex-A9 processor is in the wait for interrupt (WFI) state

The MPU provides signals to indicate when it is in a standby state. These signals are available to custom hardware designs in the FPGA fabric.

Related Information

[Cortex-A9 MPCore](#) on page 1025

For more information, refer to *Cortex-A9 MPU Subsystem*.

29.6.2. General Purpose Signals

Table 277. General Purpose Interfaces

Signal	Description	Associated Signal
<code>h2f_gp</code>	General purpose interface. Enables a pair of 32-bit unidirectional general-purpose interfaces between the FPGA manager in HPS and the FPGA fabric.	<code>h2f_gp_in</code> <code>h2f_gp_out</code>

29.6.3. FPGA-to-HPS Interrupts

You can configure the HPS component to provide 64 general purpose FPGA-to-HPS interrupts, allowing soft IP in the FPGA fabric to trigger interrupts to the MPU's generic interrupt controller (GIC). The interrupts are implemented through the following 32-bit interfaces:

- `f2h_irq0`—FPGA-to-HPS interrupts 0 through 31
- `f2h_irq1`—FPGA-to-HPS interrupts 32 through 63

The FPGA-to-HPS interrupts are asynchronous on the FPGA interface. Inside the HPS, the interrupts are synchronized to the MPU's internal peripheral clock (`periphclk`).

Related Information

[HPS Component Interfaces](#) on page 4594

There are various HPS peripherals to FPGA interrupt interfaces that you can configure. To learn the complete list of interfaces, refer to the *Instantiating the HPS Component* chapter.

29.6.4. Boot from FPGA Interface

You can enable the boot from FPGA interface to indicate the availability of preloader software in the FPGA memory. This interface is used to indicate the availability of a fallback preloader software in FPGA memory as well. The fallback preloader is used when there is no valid preloader image found in HPS flash memories.

29.6.5. Security Manager

Table 278. Anti Tamper signal

Interface Name	Description
h2f_security	HPS to FPGA input to trigger memory scrambling of all internal memories.

30. Simulating the HPS Component

This section describes the simulation support for the hard processor system (HPS) component. The HPS simulation models provide bus functional models of the HPS and FPGA fabric and a simulation model of the interface to SDRAM memory.

The HPS simulation support does not include modules implemented in the HPS, such as the Arm Cortex-A9 MPCore processor.

The simulation support files are specified when the HPS component is instantiated in the Platform Designer system integration tool. When you enable a particular HPS-FPGA interface, Platform Designer provides the corresponding model during the generation process.

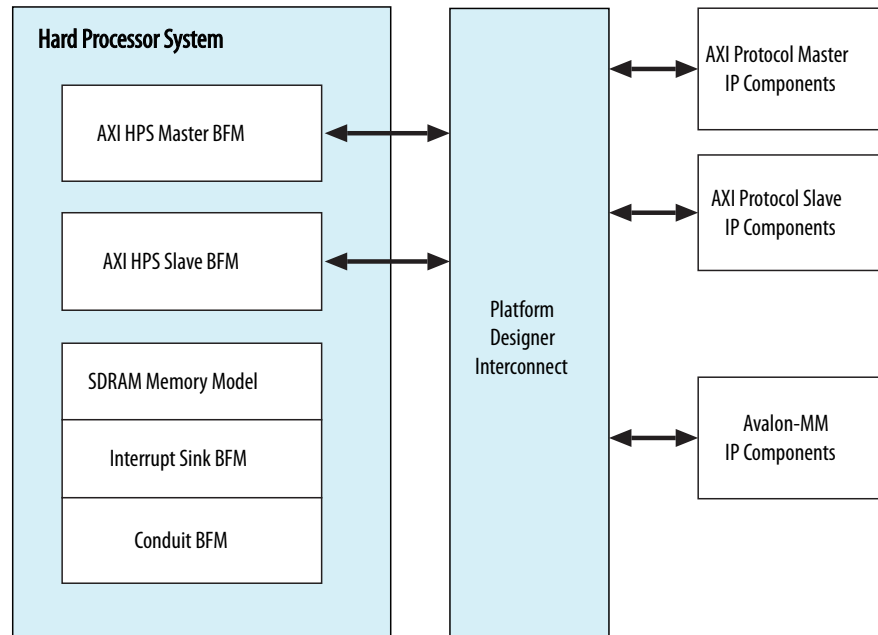

The HPS simulation support enables you to develop and verify your own FPGA user logic or intellectual property (IP) that interfaces to the HPS component.

The simulation model supports the following interfaces:

- Clock and reset interfaces
- FPGA-to-HPS Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) slave interface
- HPS-to-FPGA AXI master interface
- Lightweight HPS-to-FPGA AXI master interface
- Microprocessor unit (MPU) general-purpose I/O (GPIO) interface
- MPU standby and event interface
- Interrupts interface
- Direct memory access (DMA) controller peripheral request interface
- Debug Advanced Peripheral Bus (APB) interface
- System Trace Macrocell (STM) hardware event
- FPGA cross trigger interface (CTI)
- FPGA trace port interface unit (TPIU)
- Boot from FPGA interface

Figure 196. HPS BFM Block Diagram

The HPS BFMs use standard function calls from the BFM application programming interface (API), as detailed in the remainder of this chapter.

HPS simulation supports only Verilog HDL or SystemVerilog simulation environments. Users with VHDL Custom IP can run BFM simulations so long as a mixed-language simulation license is available on their chosen simulator.

30.1. Simulation Flows

Intel provides a functional register transfer level (RTL) simulation and a post-fitter gate-level simulation flow. Both simulation flows involve the following major steps, which is defined in the following sections:

1. Setting up the HPS component for simulation.
2. Generating the HPS simulation model in Platform Designer.
3. Running the simulation.

Related Information

[Simulating Altera FPGA Designs](#)

For general information about simulation, refer to the *Simulating Altera FPGA Designs* chapter in volume 3 of the *Quartus Prime Standard Edition Handbook*.

30.1.1. Setting Up the HPS Component for Simulation

The following steps outline how to set up the HPS component for simulation.

1. Add the HPS component from the Platform Designer Component Library.
2. Configure the component based on your application needs by selecting or deselecting the HPS-FPGA interfaces.
3. Connect the appropriate HPS interfaces to other components in the system. For example, connect the FPGA-to-HPS AXI slave interface to an AXI or Avalon-MM master interface in another component in the system.

When you create your component, make sure the conduit interfaces have the correct role names and widths. Also make sure the conduit interfaces are opposite in direction to what is shown in the HPS Conduit Interfaces table.

30.1.2. Generating the HPS Simulation Model in Platform Designer

The following steps outline how to generate the simulation model:

1. In Platform Designer, click **Generate HDL** under the Generate menu.
2. Choose between RTL and post-fit simulation
 - For RTL simulation, perform the following steps:
 - a. Set **Create simulation model** to Verilog.
 - b. Click **Generate**.⁽⁶⁰⁾
 - For post-fit simulation, perform the following steps:
 - a. Turn on the **Create HDL design files for synthesis** option.
 - b. Turn on the **Create block symbol file (.bsf)** option.⁽⁶¹⁾⁽⁶²⁾
3. Click **Generate**.

Related Information

- [Instantiating the HPS Component](#)
- [Platform Designer User Guide: Intel Quartus Prime Pro Edition](#)
For more information about Platform Designer simulation, refer to Platform Designer User Guide: Intel Quartus Prime Pro Edition.

30.1.3. Running the Simulations

The steps to run a simulation depend on whether you are running an RTL simulation or a post-fit simulation.

⁽⁶⁰⁾ VHDL is supported for HPS simulation and it requires a mix language simulator. However, the BFM's always need to be in verilog. Custom components can be in VHDL.

⁽⁶¹⁾ A **.bsf** file is only needed for schematic entry.

⁽⁶²⁾ This is not a requirement for simulation or implementation unless a schematic is used.

30.1.3.1. Running HPS RTL Simulation

Platform Designer generates scripts for several simulators that you can use to complete the simulation process, as listed in the following table.

Table 288. Platform Designer-Generated Scripts for Supported Simulators

Simulator	Script Name	Directory
ModelSim* - Intel FPGA Edition	msim_setup.tcl	<project directory>/<Platform Designer design name>/simulation/mentor
Cadence NC-Sim	ncsim_setup.sh	<project directory>/<Platform Designer design name>/simulation/cadence
Synopsys VCS	vcs_setup.sh	<project directory>/<Platform Designer design name>/simulation/synopsys/vcs
Synopsys VCS-MX	vcsmx_setup.sh	<project directory>/<Platform Designer design name>/simulation/synopsys/vcsmx
Aldec* RivieraPro™	rivierapro_setup.tcl	<project directory>/<Platform Designer design name>/simulation/aldec

Related Information

- [Mentor Verification IP Edition AMBA AXI3TM/AXI4TM User Guide](#)

30.1.3.2. Running HPS Post-Fit Simulation

To run HPS post-fit simulation after successful Platform Designer generation, perform the following steps:

1. Add the generated synthesis file set to your Intel Quartus Prime project by performing the following steps:
 - a. In the Intel Quartus Prime software, click **Settings** in the Assignments menu.
 - b. In the **Settings** <your Platform Designer system name> dialog box, on the **Files** tab, browse to <your project directory>/<your Platform Designer system name>/synthesis/ and select <your Platform Designer system name>.qip.
 - c. Click **Open**. The **Select File** dialog box closes.
 - d. Click **OK**. The **Settings** dialog box closes.
2. Optionally instantiate your HPS system as the top-level entity in your Intel Quartus Prime project.
3. Compile the design by clicking **Start Compilation** in the Processing menu.
4. Change the EDA Netlist Writer settings, if necessary, by performing the following steps:
 - a. Click **Settings** in the Assignment menu.
 - b. On the **Simulation** tab, under the **EDA Tool Settings** tab, you can specify the following EDA Netlist Writer settings:

- **Tool name**—The name of the simulation tool
 - **Format for output netlist**
 - **Output directory**
- c. Click **OK**.
5. To create the post-fitter simulation model with Quartus Prime EDA Netlist Writer, perform the following steps:
- a. Click **Start** in the Processing menu.
 - b. Click **Start EDA Netlist Writer**.

Related Information

[Quartus Prime Help](#)

30.1.3.2.1. Post-Fit Simulation Files

Post-fit simulation is the simulation of the netlist generated from the original RTL design after it has been mapped, synthesized, and fit. The netlist represents the actual hardware and its connections as they appear in the FPGA. Quartus Prime generates the netlist and can generate a Standard Delay Format (.sdf) file with the timing information for all connections. The simulation can be functional only (without the timing information) where all wires and gates take zero time, or it can be a timing simulation where the time for all transitions is based on the SDF information.

Post-fit simulation can serve a number of different purposes. It can be used to perform a dynamic verification of the timing of the design, or it can be used to verify the functional correctness of either the design, the compilation flow (in particular, the fitter), or both.

This table uses the following symbols:

30.1.3.2.2. BFM API Hierarchy Format

For post-fit simulation, you must call the BFM API in your test program with a specific hierarchy. The hierarchy format is:

```
<DUT>.\<HPS>|fpga_interfaces|
<interface><space>.<BFM>.<API function>
```

⁽⁶³⁾ The device simulation library is not needed with ModelSim - Intel FPGA Edition.

Where:

- **<DUT>** is the instance name of the design under test that you instantiated in your test bench. The design under test is the HPS component.
- **<HPS>** is the HPS component instance name that you use in your Platform Designer system.
- **<interface>** is the instance name of a specific FPGA-to-HPS or HPS-to-FPGA interface. This name can be found in the `fpga_interfaces.sv` file located in `<project directory>/<Platform Designer design name>/synthesis/submodules`.
- **<space>**—You must insert one space character after the interface instance name.
- **<BFM>** is the BFM instance name. To identify the BFM instance name, in `<ACDS install>/ip/altera/hps/postfitter_simulation`, find the SystemVerilog file corresponding to the interface type that you are using. This SystemVerilog file contains the BFM instance name.

For example, a path for the Lightweight HPS-to-FPGA master interface hierarchy could be formed as follows:

```
top.dut.\my_hps_component|fpga_interface|  
hps2fpga_light_weight .h2f_lw_axi_master
```

Notice the space after `hps2fpga_light_weight`. Omitting this space would cause simulation failure because the instance name `hps2fpga_light_weight`, including the space, is the name used in the post-fit simulation model generated by the Quartus Prime software.

30.2. Clock and Reset Interfaces

30.2.1. Clock Interface

Platform Designer generates the clock source BFM for the FPGA-to-HPS alternate clock source.

Table 290. HPS Clock Input Interface Simulation Model

The clock source BFM application programming interface (API) applies to the BFM listed in this table. Your Verilog interfaces use the same API.

Interface Name	BFM Instance Name
f2h_free_clk	f2h_free_clock_inst

Platform Designer generates the clock source BFM for each clock output interface from the HPS component. For HPS-to-FPGA user clocks, specify the BFM clock rate in the **User clock frequency field** in the **HPS Clocks** page when instantiating the HPS component in Platform Designer.

The HPS-to-FPGA debug APB interface generates a clock output to the FPGA, named `h2f_debug_apb_clock`. In simulation, the clock source BFM also represents this clock output's behavior.

**Table 291. HPS Clock Output Interface Simulation Model**

The Intel clock source BFM application programming interface (API) applies to all the BFM's listed in this table. Your Verilog interfaces use the same API.

Interface Name	BFM Instance Name
h2f_user0_clock	h2f_user0_clock_inst
h2f_user1_clock	h2f_user1_clock_inst
h2f_user2_clock	h2f_user2_clock_inst

30.2.2. Reset Interface

The HPS reset request and handshake interfaces are connected to conduit BFM's for simulation.

Table 292. HPS Reset Input Interface Simulation Model

You can monitor the reset request interface state changes or set the interface by using the API listed.

Interface Name	BFM Instance Name	API Function Names
f2h_cold_reset_req	f2h_cold_reset_req_inst	get_f2h_cold_rst_req_n()
f2h_debug_reset_req	f2h_debug_reset_req_inst	get_f2h_dbg_rst_req_n()
f2h_warm_reset_req	f2h_warm_reset_req_inst	get_f2h_warm_rst_req_n()
h2f_warm_reset_handshake	h2f_warm_reset_handshake_inst	set_h2f_pending_rst_req_n() get_f2h_pending_rst_ack_n()

Table 293. HPS Reset Output Interface Simulation Model

The reset source BFM application programming interface applies to all the BFM's listed.

Interface Name	BFM Instance Name
h2f_reset	h2f_reset_inst
h2f_cold_reset	h2f_cold_reset_inst
h2f_debug_apb_reset	h2f_debug_apb_reset_inst

Table 294. Configuration of Reset Source BFM for HPS Reset Output Interface

The HPS reset output interface is connected to a reset source BFM. Platform Designer configures the BFM as shown in the following table. The parameter value of the instantiated BFM is configured for HPS simulation.

Parameter	BFM Value	Meaning
Assert reset high	Off	This parameter is off, specifying an active-low reset signal from the BFM.
Cycles of initial reset	0	This parameter is 0, specifying that the BFM does not assert the reset signal automatically.

30.3. FPGA-to-HPS AXI Slave Interface

The FPGA-to-HPS AXI slave interface, `f2h_axi_slave`, is connected to a Mentor Graphics® AXI slave BFM for simulation with an instance name of `f2h_axi_slave_inst`. Platform Designer configures the BFM as shown in the following table. The BFM clock input is connected to `f2h_axi_clock` clock.

Table 295. Configuration of FPGA-to-HPS AXI Slave BFM

Parameter	Value
AXI Address Width	32
AXI Read Data Width	32, 64, or 128
AXI Write Data Width	32, 64, or 128
AXI ID Width	8

You control and monitor the AXI slave BFM by using the BFM API.

30.4. HPS-to-FPGA AXI Master Interface

The HPS-to-FPGA AXI master interface, `h2f_axi_master`, is connected to a Mentor Graphics AXI master BFM for simulation with an instance name of `h2f_axi_master_inst`. In Platform Designer, you can configure the HPS-to-FPGA interface with the following address, data, and ID widths. The BFM clock input is connected to `h2f_axi_clock` clock.

Table 296. Configuration of HPS-to-FPGA AXI Master BFM

Parameter	Value
AXI Address Width	30
AXI Read and Write Data Width	32, 64, or 128
AXI ID Width	12

You control and monitor the AXI master BFM by using the BFM API.

30.5. Lightweight HPS-to-FPGA AXI Master Interface

The lightweight HPS-to-FPGA AXI master interface, `h2f_lw_axi_master`, is connected to a Mentor Graphics AXI master BFM for simulation with an instance name of `h2f_lw_axi_master_inst`. Platform Designer configures the BFM as shown in the following table. The BFM clock input is connected to `h2f_lw_axi_clock` clock.

Table 297. Configuration of Lightweight HPS-to-FPGA AXI Master BFM

Parameter	Value
AXI Address Width	21
AXI Read and Write Data Width	32
AXI ID Width	12

You control and monitor the AXI master BFM by using the BFM API.

30.9. FPGA-to-HPS System Trace Macrocell Hardware Event Interface

The FPGA-to-HPS STM hardware event interface is connected to a conduit BFM for simulation. The following table lists the name of each interface, along with the API function name for each type of simulation. You can monitor the interface state changes or set the interface by using the API functions listed.

Table 302. FPGA-to-HPS STM Hardware Event Interface Simulation Model

Interface Name	BFM Name	RTL Simulation API Function Name	Post-Fit Simulation API Function Name
f2h_stm_hw_events	f2h_stm_hw_events_inst	get_f2h_stm_hwevents()	get_stm_events()

30.10. HPS-to-FPGA Cross-Trigger Interface

The HPS-to-FPGA cross-trigger interface is connected to a conduit BFM for simulation. The following table lists the name of each interface, along with API function names for each type of simulation. You can monitor the interface state changes or set the interface by using the API functions listed.

Table 303. HPS-to-FPGA Cross-Trigger Interface Simulation Model

Interface Name	BFM Name	RTL Simulation API Function Names	Post-Fit Simulation API Function Names
h2f_cti	h2f_cti_inst	get_h2f_cti_trig_in()	get_trig_in()
		set_h2f_cti_trig_in_ack()	set_trig_inack()
continued...			

Interface Name	BFM Name	RTL Simulation API Function Names	Post-Fit Simulation API Function Names
		set_h2f_cti_trig_out()	set_trig_out()
		get_h2f_cti_trig_out_ack()	get_trig_outack()
		get_h2f_cti_fpga_clk_en()	get_clk_en()

30.11. FPGA-to-HPS DMA Handshake Interface

The FPGA-to-HPS DMA handshake interface is connected to a conduit BFM for simulation. The following table lists the name for each interface, along with API function names for each type of simulation. You can monitor the interface state changes or set the interface by using the API listed.

Table 304. FPGA-to-HPS DMA Handshake Interface Simulation Model

The usage of conduit `get_*()` and `set_*()` API functions is the same as with the general Avalon conduit BFM.

Interface Name	BFM Instance Name	RTL Simulation API Function Names	Post-Fit Simulation API Function Names
f2h_dma0	f2h_dma0_inst	get_f2h_dma0_req() get_f2h_dma0_single() set_f2h_dma0_ack()	get_channel0_req() get_channel0_single() set_channel0_xx_ack()
f2h_dma1	f2h_dma1_inst	get_f2h_dma1_req() get_f2h_dma1_single() set_f2h_dma1_ack()	get_channel1_req() get_channel1_single() set_channel1_xx_ack()
f2h_dma2	f2h_dma2_inst	get_f2h_dma2_req() get_f2h_dma2_single() set_f2h_dma2_ack()	get_channel2_req() get_channel2_single() set_channel2_xx_ack()
f2h_dma3	f2h_dma3_inst	get_f2h_dma3_req() get_f2h_dma3_single() set_f2h_dma3_ack()	get_channel3_req() get_channel3_single() set_channel3_xx_ack()
f2h_dma4	f2h_dma4_inst	get_f2h_dma4_req() get_f2h_dma4_single() set_f2h_dma4_ack()	get_channel4_req() get_channel4_single() set_channel4_xx_ack()
f2h_dma5	f2h_dma5_inst	get_f2h_dma5_req() get_f2h_dma5_single() set_f2h_dma5_ack()	get_channel5_req() get_channel5_single() set_channel5_xx_ack()

30.12. Boot from FPGA Interface

The boot from FPGA interface is connected to a conduit BFM for simulation. You can monitor the interface state changes or set the interface by using the API functions in the table below.

Table 305. Boot from FPGA Interface Simulation Model

Interface Name	BFM Name	RTL simulation API Function Names	Post-fit Simulation API Function Names
f2h_boot_from_fpga	f2h_boot_from_fpga_inst	get_f2h_boot_from_fpga_read_y() get_f2h_boot_from_fpga_on_failure()	get_boot_fpga_ready() get_boot_from_fpga_on_failure()

30.13. Security Manager Anti-Tamper Signals Interface

The security manager anti-tamper signals interface is connected to a conduit BFM for simulation. You can monitor the interface state changes or set the interface by using the API listed.

Table 306. Security Manager Anti-Tamper Signals Interface Simulation Model

Interface Name	BFM Instance Name	RTL Simulation API Function Names
h2f_security	h2f_security_inst	get_f2h_security_anti_tamper_in set_h2f_security_anti_tamper_out

30.14. EMIF Conduit

Enables the HPS dedicated conduit to the Arria 10 External memory Interface for HPS. This conduit cannot connect to any other External memory Interface (EMIF). Only IP generated by the Arria 10 External memory Interface for HPS Platform Designer library should be used.

Table 307. EMIF Conduit Interface Simulation Model

Interface Name	BFM Instance Name	RTL Simulation API Function Names
emif	emif_inst	emif_emif_to_hps emif_hps_to_emif

30.15. Pin MUX and Peripherals

Under Pin MUX and Peripherals, the **Pin Mux GUI** has three folder tabs with the following functions:

- IP Selection
- Advanced Pin Placement
- Advanced FPGA Placement

The **IP Selection** tab contains two sub-windows. In the left sub-window, you are able to select the following:

- Boot source — SD/MMC, NAND, and QSPI
- Pin routing decisions between:
 - IP and HPS I/O—where your selections are reflected on the **Advanced Pin Placement**
 - IP and FPGA—where your selections are reflected on the **Advanced FPGA Placement**
- NAND bit-width when the NAND IP is selected
- SD/MMC bit-width and SD/MMC Power Enable when the SD/MMC IP is selected
- RGMII and PHY Options for each of the EMACs when the EMAC IP is selected
- Additional QSPI Slave Selects when the QSPI IP is selected

After you have made your selection, you must click on the **Apply Selections** button and select "Show signals" so that you can see your selection reflected in the right sub-window. Depending on if you are routing to the HPS I/O or the FPGA, your selection is reflected on the **Advanced Pin Placement** or **Advanced FPGA Placement** tab, respectively.

A. Booting and Configuration

The Intel system-on-a-chip (SoC) device provides a variety of ways to boot the hard processor system (HPS) and configure the FPGA portion.

Related Information

[Intel Arria 10 Hard Processor System Technical Reference Manual Revision History](#) on page 17

For details on the document revision history of this chapter

A.1. Boot Overview

The boot flow of the HPS is a multi-stage process. Each stage is responsible for loading the next stage.

The first stage is the boot ROM execution. The boot ROM code, located in the HPS, brings the processor out of reset, puts the processor into a known and stable state, finds the second-stage boot loader and passes control to the next stage. The boot ROM code is only aware of the second-stage boot loader and not aware of any potential subsequent software stages. During this time, the boot ROM also seamlessly handles any error conditions that may occur.

The next stage is when control passes to the second-stage boot loader. The second-stage boot loader is located external to the HPS, either in off-chip flash memory or within the FPGA. If the FPGA is used, the second stage boot loader can execute directly from the FPGA without the need to copy it to on-chip RAM. The second stage-boot loader locates and loads the next stage software and so on.

Before the control is passed to the second stage boot loader, it can be decrypted and/or authenticated if a secure boot is enabled.

After a warm reset, the user can program the HPS to instruct the boot ROM to find an image in the on-chip RAM and execute directly from that. In this case, the image that resides in RAM is unauthenticated and clear text, although it may have been imported into on-chip RAM as authenticated code initially.

The figure below illustrates the typical boot flow. However, there may be more or less software stages in the user software than shown and the roles of the software stages may vary.

Figure 197. Typical Boot Flow

A.2. FPGA Configuration Overview

After power is applied to the FPGA and HPS portion of the SoC, configuration may begin. The FPGA may be configured through a variety of ways, such as through the HPS, JTAG, or an external host.

The Configuration Subsystem (CSS) in the FPGA portion of the device is responsible for obtaining an FPGA configuration image and configuring the FPGA fabric, as well as the IOCSRs (I/O Configuration and Status Registers). The I/O configuration file programs the following in the IOCSRs:

- FPGA I/O
- Shared I/O
- Hard memory controller I/O
- Hard memory controller settings, such as memory type, frequency and timings
- FPGA PLL settings
- Transceiver settings

The FPGA configuration ends when the configuration image has been fully loaded and the FPGA enters user mode. The FPGA configuration image is typically stored in external non-volatile flash-based memory. The FPGA Configuration Subsystem can obtain a configuration image from the HPS through the FPGA Manager or from any of the sources supported by the FPGA family.

Related Information

A.3. Booting and Configuration Options

SoC initialization includes the booting of the HPS and the configuration of the FPGA fabric and I/O.

The I/O provided in the SoC are:

- HPS dedicated I/O that are configured by the HPS
- Shared I/O used by the HPS or FPGA and configured by the Intel Quartus Prime I/O configuration file.
- FPGA I/O configured by the Intel Quartus Prime I/O configuration file.
- Hard memory controller I/O shared by the HPS and FPGA and configured by the Intel Quartus Prime I/O configuration file.

Depending on the initialization option you choose, the I/O configuration is handled differently. You can choose one of the three initialization options:

- The HPS boot and FPGA configuration occur separately.
- The HPS boots first and then configures the FPGA.
- The HPS boots from the FPGA after the FPGA is configured.

Note: The HPS and FPGA fabric must be powered at the same time. You must not power-down the HPS or FPGA independently in the middle of device operation.

The following three figures illustrate the possible HPS boot and FPGA configuration schemes. The arrows in the figures denote the data flow direction.

Figure 198. Separate FPGA Configuration and HPS Booting

In the figure below, the FPGA configuration and HPS boot can occur separately. The FPGA obtains its configuration image from a non-HPS source. The source is sent to the CSS block which configures the FPGA fabric, FPGA I/O, shared I/O, hard memory controller I/O and other settings. If the hard memory controller or shared I/O are required by the HPS, then the FPGA fabric and I/O (FPGA, shared and hard memory controller) configuration must be complete before the HPS can boot.

The HPS boot ROM obtains its second-stage boot loader from a non-FPGA fabric source. The second-stage boot loader should contain the configuration for the HPS dedicated I/O.

For more information about FPGA configuration, refer to the "FPGA Configuration" section.

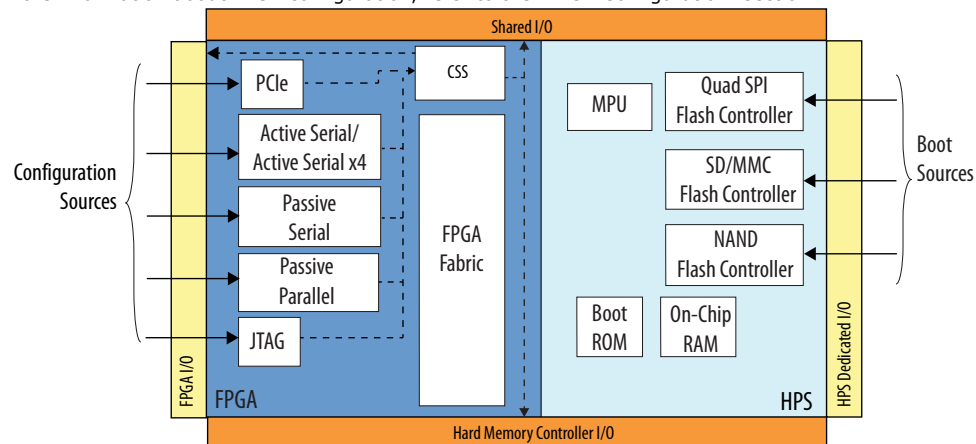

Figure 199. HPS Boots First and then Configures the FPGA

In the figure below, the HPS boots first through one of its non-FPGA fabric boot sources. If the hard memory controller or shared I/O are required by the HPS during booting then you can either execute a full FPGA configuration flow or an early I/O release configuration flow. The FPGA must be in a power-on state for the HPS to reset properly and for the second stage boot loader to initiate configuration through the FPGA Manager. The software executing on the HPS obtains the FPGA configuration image from any of its flash memory devices. For more information about full FPGA configuration or early I/O release configuration after HPS booting, refer to the "FPGA Configuration" section.

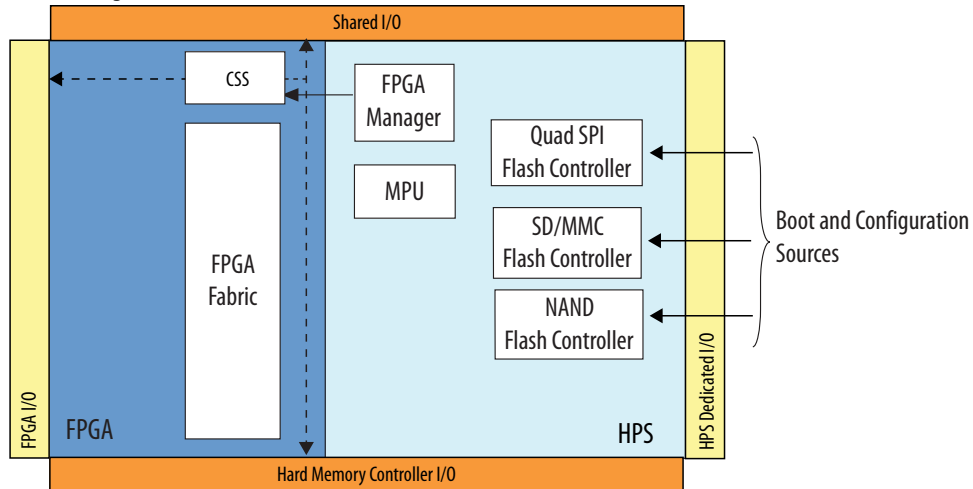

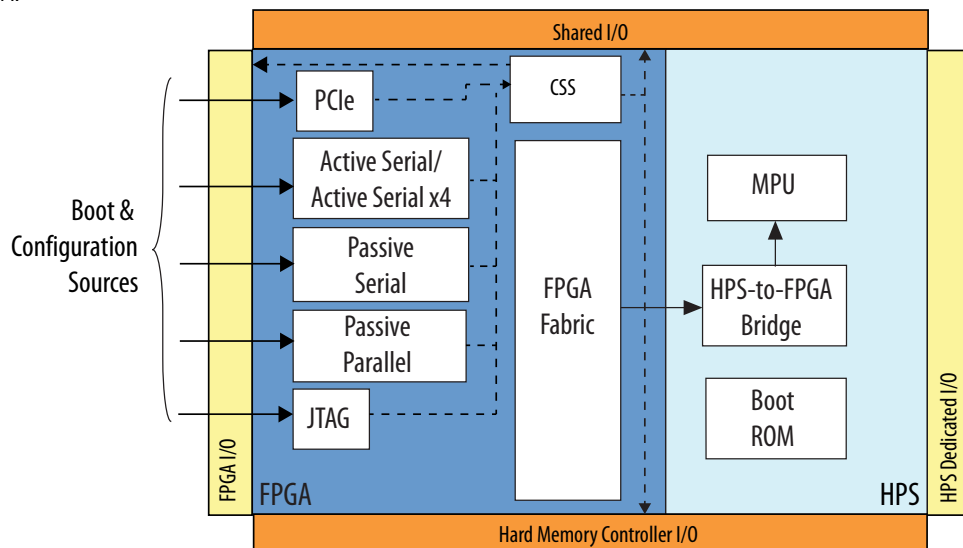

Figure 200. HPS Boots From FPGA

In the figure below, the FPGA is configured first through one of its non-HPS configuration sources. The CSS block configures the FPGA fabric as well as the FPGA I/O, shared I/O and hard memory controller I/O. The HPS boot ROM code executes the second-stage boot loader from the FPGA fabric over the HPS-to-FPGA bridge.

You can select a boot from FPGA by setting the BSEL value to 0x1. If the fpga_boot_f fuse is blown then the FPGA is always selected as the boot source. In both cases, when the FPGA is selected as the boot source, the CSEL fuses are ignored and clock configuration is controlled through the second-stage boot loader code in the FPGA.

A.4. Boot Definitions

The following sections contain basic terms and definitions that are part of the boot process.

A.4.1. Reset

Reset precedes the boot stages and is an important part of device initialization. There are two different reset types: cold reset and warm reset.

The FPGA portion of the SoC can trigger a warm or cold reset on completion of configuration.

The boot process begins when CPU0 in the MPU exits from the reset state. When CPU0 exits from reset, it starts executing code at the reset exception address where the boot ROM code is located. CPU1 remains in reset during this time and is brought out of reset by user software.

With warm reset, some software registers are preserved and the boot process may skip some steps depending on software settings. In addition, on a warm reset, the second-stage boot loader has the ability to be executed from on-chip RAM.

Note: It is important that the HPS is not held in cold or warm reset indefinitely, otherwise the CSS will not be accessible to FPGA configuration sources.

A.4.2. Boot ROM

The boot ROM code is 128 KB in size and located in on-chip ROM at address range 0xFFFC0000 to 0xFFDFFFFF. The function of the boot ROM code is to determine the boot source, initialize the HPS after a reset, and jump to the second-stage boot loader. In the case of indirect execution, the boot ROM code loads the second-stage boot loader image from the flash memory to on-chip RAM. The boot ROM performs the following actions to initialize the HPS:

- Enable instruction cache, branch predictor, floating point unit, NEON vector unit of CPU0
- Sets up the level 4 (L4) watchdog 0 timer
- Initializes the flash controller to default settings
- Configures HPS dedicated I/O

When booting from flash memory, the boot ROM code uses the top 32 KB of the on-chip RAM as data workspace. This area is reserved for the boot ROM code after a reset until the boot ROM code passes software control to second-stage boot loader. The maximum second-stage boot loader size is 208 KB with authentication and 224 KB

without. For a warm reset or cold reset with a boot from FPGA, the boot ROM code does not reserve the top 32 KB of the on-chip RAM, and the user may place user data in this area without being overwritten by the boot ROM.

The boot process begins when CPU0 exits from the reset state. The boot ROM code only executes on CPU0. CPU1 is held in reset while boot ROM executes on CPU0. When a CPU0 exits from reset, it starts executing code at the reset exception address.

During boot ROM execution, the clock control fuse information is automatically sent to the Clock Manager, the memory control fuse information is automatically sent to the Reset Manager and all other fuse functions (authentication, encryption, private and public key source, hash functions) are stored in a memory-mapped location for boot code to read. In normal operation, the boot ROM is mapped at the reset exception address so code starts executing in the boot ROM.

When CPU0 exits the boot ROM code and starts executing user software, the boot ROM access is disabled. The user software in CPU0 must map the user software exception vectors at 0x0 (which is previously mapped to boot ROM exception vectors). The user software also has the option of releasing CPU1 from reset. If CPU1 is released from reset, CPU1 executes the user software exception instead of boot ROM.

A.4.3. Boot Select

The boot select (BSEL) pins offer multiple methods to obtain the second-stage boot image. On a cold reset, the boot source is determined by a combination of secure boot fuses and BSEL pins. These fuse values and BSEL pin values are sent to the Security Manager module of the HPS when the cold reset occurs. When the HPS is released from reset, the boot ROM reads the `bootinfo` register of the System Manager to determine the source of the boot.

Note: If the `fpga_boot_f` fuse is blown, the BSEL pins are bypassed and the HPS can only boot from the FPGA. Additionally, the clock select (CSEL) fuse values are ignored and clock configuration is controlled through the FPGA. This configuration allows the HPS to boot from encrypted user code in the FPGA. If the boot source is the FPGA, the boot ROM code does not configure any of the boot-specific HPS I/Os for booting from flash memory. If the `fpga_boot_f` fuse is not blown, then the boot source is determined according to the BSEL pins. If the BSEL pins are used for determining the boot source, then the following table shows the flash devices assigned to each encoding.

Note: When booting from FPGA is selected (`BSEL[2:0]=0x1`), the Boot ROM waits until the FPGA is in user mode, and then it queries the handshake signals, `f2h_boot_from_fpga_ready` and `f2h_boot_from_fpga_on_failure`, from the FPGA to the HPS. The `f2h_boot_from_fpga_ready` signal must be pulled up to indicate readiness. Refer to the *Instantiating the HPS Component* chapter for more information about the FPGA boot handshake signals.

Note: The acronyms BSEL and BOOTSEL are used interchangeably to define the boot select pins.

Table 338. BSEL Values for Boot Source Selection

BSEL[2:0] Value	Flash Device
0x0	Reserved
0x1	FPGA (HPS-to-FPGA bridge)
0x2	1.8 V NAND flash memory
0x3	3.0 V NAND flash memory
0x4	1.8 V SD/MMC flash memory with external transceiver
0x5	3.0 V SD/MMC flash memory with internal transceiver
0x6	1.8 V quad SPI flash memory
0x7	3.0 V quad SPI flash memory

Note: During the HPS boot phase, the boot ROM only recognizes 1.8 V or 3.0 V dedicated I/O operation. If your dedicated I/O are operating at 2.5 V, then your BSEL value must be set to 3.0 V to support your operating I/O voltage at boot. After booting has completed, you may configure your dedicated I/O voltage settings to the true level by programming the `configuration_dedicated_io_bank` and `configuration_dedicated_io_*` registers in the `io48_pin_mux_dedicated_io_grp` address block.

Note: If the BSEL value is set to 0x4 or 0x5, an external translation transceiver may be required to supply level-shifting and isolation if the SD cards interfacing to the SD/MMC controller must operate at a different voltage than the controller interface. Please refer to the *SD/MMC Controller* chapter for more information.

The typical boot flow is for the boot ROM code to find the second-stage boot loader image on a flash device, load that into on-chip RAM and execute it. After a warm reset, the boot ROM code can be instructed to find the image in RAM and execute that.

The HPS flash sources can store various file types, such as:

- FPGA programming files
- Second-stage boot loader binary file (up to four copies)
- Operating system binary files
- Application file system

The second-stage boot loader image in flash can be authenticated and decrypted by the HPS. A boot directly from the HPS on-chip RAM is always unauthenticated and in clear text, although it may have an optional CRC if required.

When the BSEL value is 0x1, the FPGA is selected as the boot source for that boot. This selection is not permanent as it is when the `fpga_boot_f` fuse is enabled. In both cases, the CSEL fuses are also ignored and the HPS must be held in reset until the FPGA is powered on and programmed to prevent the boot ROM from misinterpreting the boot source.

If an HPS flash interface has been selected to load the boot image, then the boot ROM enables and configures that interface before loading the boot image into on-chip RAM, verifying it and passing software control to the second-stage boot loader.

If the FPGA fabric is the boot source, the boot ROM code waits until the FPGA portion of the device is in user mode, and is ready to execute code and then passes software control to the second-stage boot loader in the FPGA RAM.

A.4.3.1. Boot Source I/O Pins

The HPS has 17 dedicated I/O pins. Three are used as a clock, cold reset and warm reset pin. The warm reset signal is a bidirectional signal; a warm reset event can drive into the HPS, or a warm reset event can be generated by the HPS and drive out of this pin.

The remaining 14 dedicated I/O pins are used for boot devices as well as other peripherals. Three of these 14 dedicated I/O pins are sampled by software at either cold or warm reset and convey boot source information. The following table identifies the pin mux values for the boot source options.

Table 339. Boot Source MUX Selects

This table identifies the dedicated HPS signals that are mapped to each boot interface and the mux select value each boot interface signal requires. Note that Clock Manager clock inputs are also assigned to MUX select 4 and are documented here for thoroughness.

Signal	MUX Select		
	14	8	4

A.4.3.2. Boot Fuses

During boot ROM execution, the boot ROM reads user-programmed fuses that configure the boot state of the HPS.

These fuse values are read by the Configuration Subsystem (CSS) after power-up and to the Security Manager where they are read by the boot ROM. The following list describes the basic fuses that affect the state of the HPS:

- Clock select fuses: Determine the clock frequencies of the MPU clock, the interconnect clocks and the peripheral clocks.
- Debug fuses: Determine the state of debug during the boot process and during hand-off to the second-stage boot loader.
- RAM fuses: Determine whether or not the various peripheral RAMs are cleared during a warm reset and how they are cleared (series or parallel).

- Boot fuses: Determines whether the second-stage boot loader is from on-chip RAM, whether an internal or external clock is used for booting and whether the boot source is solely from FPGA.
- Security fuses: Determines whether the second-stage boot loader is authenticated or decrypted. If authentication is used, then there are fuses that are read by the boot ROM to determine where the key authorization key (KAK) resides and what its length is.
- User fuses: The user fuses may either hold proprietary user information or may hold the value of the KAK.

Table 341. HPS_fusesec Register Description

Bits	Name	Description
31:27	Reserved	Bit values in this field are undefined.
26:23	csel_f	This field indicates the value of the clock select fuses that are available for configuring the clock for the boot interface and for the PLLs. Refer to the <i>Clock Configuration</i> section for more information on CSEL encodings.
22	dbg_access_f	This fuse determines the initial state of the debug access domains.
21	dbg_lock_JTAG	This field indicates if the HPS JTAG access level can be changed through software when the HPS is released from reset. <ul style="list-style-type: none"> • 0x0= HPS JTAG access level can be changed through the sec_jtagdbg register. • 0x1= HPS JTAG access level cannot be changed (locked).

A.4.4. Flash Memory Devices for Booting

The memory controllers and devices that contain the boot loader image have configuration requirements for proper boot from flash.

On all flash devices, there is an area of memory, called the boot area that contains up to four second-stage boot loader images. For the QSPI and SD/MMC devices, the boot area is 1 MB in size. For NAND devices the boot area is four device blocks in size and may be larger than 1 MB if the NAND erase block is larger than 256 KB.

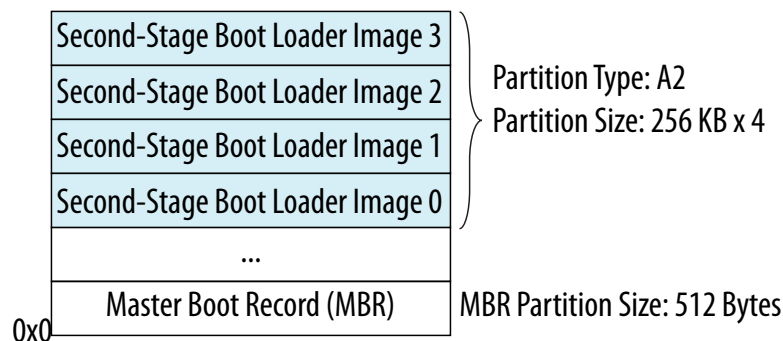

The SD/MMC, Quad SPI and NAND flash devices all support raw and MBR (partition) mode. In raw mode, the boot image is located at the start of the flash memory device, at offset 0x0. In MBR mode:

- The boot image is read from a custom partition (0xA2)
- The first image is located at the beginning of the partition, at offset 0x0
- Start address = partition start address

A.4.4.1. SD/MMC Flash Devices

The following figure shows an SD/MMC flash image layout example for boot. The master boot record (MBR) is located in the first 512 bytes of the memory. The MBR contains information about the partitions (address and size of partition). The second-stage boot loader image is stored in partition A2. Partition A2 is a custom raw partition with no file system.

Figure 201. SD/MMC Flash Image Layout

The SD/MMC controller supports two booting modes:

- MBR (partition) mode
 - The boot image is read from a custom partition (0xA2)
 - The first image is located at the beginning of the partition, at offset 0x0
 - Start address = partition start address
- Raw mode
 - If the MBR signature is not found, SD/MMC driver assumes it is in raw mode
 - The boot image data is read directly from sectors in the user area and is located at the first sector of the SD/MMC
 - The first image is located at the start of the memory card, at offset 0x0
 - Start address = 0x0

The MBR contains the partition table, which is always located in the first sector (LBA0) with a memory size of 512 bytes. The MBR consists of executable code, four partition entries, and the MBR signature. A MBR can be created by specific tools like the FDISK program.

**Table 342. MBR Structure**

Offset	Size (In Bytes)	Description
0x000	446	Code area
0x1BE	16	Partition entry for partition 1
0x1CE	16	Partition entry for partition 2
0x1DE	16	Partition entry for partition 3
0x1EE	16	Partition entry for partition 4
0x1FE	2	MBR signature: 0xAA55

The standard MBR structure contains a partition with four 16-byte entries. Thus, memory cards using this standard table cannot have more than four primary partitions or up to three primary partitions and one extended partition.

Each partition type is defined by the partition entry. The boot images are stored in a primary partition with custom partition type (0xA2). The SD/MMC flash driver does not support a file system, so the boot images are located in partition A2 at fixed locations.

Table 343. Partition Entry

Offset	Size (In Bytes)	Description
0x0	1	Boot indicator. 0x80 indicates that it is bootable.
0x1	3	Starting CHS value
0x4	1	Partition type
0x5	3	Ending CHS value
0x8	4	LBA of first sector in partition
0xB	4	Number of sectors in partition

The boot ROM code configures the SD/MMC controller to default settings for the supported SD/MMC flash memory.

A.4.4.2. NAND Flash Devices

The NAND subsystem reserves at least the first 1 MB on the NAND device. If the NAND flash device has blocks greater than 256 KB, then the NAND subsystem reserves the first four blocks on the device. For a NAND device with less than 256 KB block size, the second-stage boot loader image must be placed in multiple blocks. The NAND subsystem expects to find up to four second-stage boot loader images on the NAND device. You may have less than four images if required. The second-stage boot loader image should always be at the start of a physical page. Because a block is the smallest area used for erase operation, any update to a particular image does not affect other images.

A.4.4.3. Quad SPI Flash Devices

The figure below shows the quad SPI flash image layout. The second-stage boot loader image is always located at offsets that are multiples of 256 KB.

Figure 203. Quad SPI Flash Image Layout

The boot ROM code configures the quad SPI controller to default settings for the supported SPI or quad SPI flash memory.

Related Information

[Quad SPI Flash Controller](#) on page 1874

Refer to the *Quad SPI Flash Controller* chapter for more information regarding features and functionality.

A.4.4.3.1. Quad SPI Controller Default Settings

Table 348. Quad SPI Controller Default Settings

Parameter	Default Setting	Register Value
SPI baud rate	Divide by 4	The master mode baud rate divisor field (bauddiv) of the quad SPI configuration register (cfg) in the quad SPI controller registers (qspiregs) = 1.
Read opcode	Refer to the "QSPI Controller Clock Options Based on CSEL and HPS_CLK Fuse Settings" table to determine the correct configuration of the HPS_CLK and CSEL fuses for Normal or Fast Reads.	The read opcode in non-XIP mode field (rdopcode) in the device read instruction register (devrd) = 0x3 (for normal read) and 0xB (for fast read).
Instruction type	Single I/O (1 bit wide)	The address transfer width field (addrwidth) and data transfer width field (datawidth) of the devrd register = 0.
Number of address bytes	3 bytes	The number of address bytes field (numaddrbytes) of the device size register (devsz) = 2. <i>Note:</i> Before a reset, you must ensure that the QSPI flash device is configured to 3 byte address mode for the boot ROM to function properly.
Delay in terms of l4_main_clk for the length that the master mode chip select outputs are deasserted between words when the clock phase is zero	The default setting in clock cycles must equal 200 ns	The clock delay for chip select deassert (field nss in the quad SPI device delay register (delay)). Refer to delay[31:24] in the "Quad SPI Flash Delay Configuration" table in the "Quad SPI Flash Delay Configuration" section for calculations.
continued...		

Parameter	Default Setting	Register Value
Delay in terms of <code>l4_main_clk</code> clock cycles between one chip select being deactivated and the activation of another. This delay ensures a quiet period between the selection of two different slaves and requires the transmit FIFO to be empty	The default setting is 0 clock cycles.	The clock delay for chip select deactivation (field <code>btwn</code> in the <code>delay</code> register = 0x0).
Delay in terms of <code>l4_main_clk</code> clock cycles between the last bit of the current transaction and the first bit of the next transaction. If the clock phase is zero, the first bit of the next transaction refers to the cycle in which the chip select is deselected	The default setting in clock cycles must equal 20 ns.	The clock delay for last transaction bit (field <code>after</code> in the <code>delay</code> register). Refer to <code>delay[15:8]</code> in the "Quad SPI Flash Delay Configuration" table in the "Quad SPI Flash Delay Configuration" section for calculations.
Added delay in terms of <code>l4_main_clk</code> clock cycles between setting <code>qspi_n_ss_out</code> low and first bit transfer	The default setting in clock cycles must equal 20 ns.	The clock delay of <code>qspi_n_ss_out</code> (field <code>init</code> in the <code>delay</code> register). Refer to <code>delay[7:0]</code> in the "Quad SPI Flash Delay Configuration" table in the "Quad SPI Flash Delay Configuration" section for calculations.

A.4.4.3.2. Quad SPI Flash Delay Configuration

The `delay` register in the quad SPI controller configures relative delay of the generation of the master output signals. All timings are defined in cycles of `l4_main_clk`.

The quad SPI flash memory must meet the following timing requirements:

- T_{SLCH} : 20 ns
 - T_{SLCH} is used to calculate the `init` field (`delay[7:0]`) in the `delay` register. The `init` field represents the delay in `l4_main_clk` clocks between pulling the device chip select (`qspi_n_ss_out`) low and the first bit transfer.
- T_{CHSH} : 20 ns
 - T_{CHSH} is used to calculate the `after` field (`delay[15:8]`) in the `delay` register. The `after` field represents the delay in the `l4_main_clk` clocks between last bit of the current transaction and the deassertion of the device chip select (`qspi_n_ss_out`).
- T_{SHSL} : 200 ns
 - T_{SHSL} is used to calculate the `nss` (`delay[31:24]`) field in the `delay` register and is the delay in the `l4_main_clk` clocks for the length that the master mode chip select outputs are deasserted between transactions.
- $T_{qspi_ref_clk}$ is the master reference clock/external clock, `l4_main_clk`.

The formulas to calculate the fields in the `delay` register are:

$$\text{delay}[7:0] = \text{init} = T_{SLCH} / T_{qspi_ref_clk}$$

$$\text{delay}[15:8] = \text{after} = T_{CHSH} / T_{qspi_ref_clk}$$

$$\text{delay}[31:24] = \text{nss} = (T_{SHSL} - T_{qspi_clk}) / T_{qspi_ref_clk}$$

Table 349. Quad SPI Flash Delay Configuration for Device Delay (delay) Register

CSEL [3:0] Fuse Values	HPS CLK Fuse Value	Input Clock Range	T _{qspi_ref_clk} (ns)	T _{qspi_clk} (ns)	delay[7:0] (init)	delay[15:8] (after)	delay[31:24] (nss)
0x0-0x1 and 0x3-0xF	1	60-200 MHz (Secure Bypass)	5	20	4	4	36
0x2	1	30-100 MHz (Secure PLL)	2.5	10	8	8	76
0x1	0	10-50 MHz (Untouched PLL)	20	80	1	1	6
0x0 and 0x2-0x6, 0xF	0	10-50 MHz (PLL Bypass)	20	80	1	1	6
0x7	0	10-15 MHz	2.5	10	8	8	76
0x8	0	15-20 MHz	2.5	10	8	8	76
0x9	0	20-25 MHz	2.5	10	8	8	76
0xA	0	25-30 MHz	2.5	10	8	8	76
0xB	0	30-35 MHz	2.5	10	8	8	76
0xC	0	35-40 MHz	2.5	10	8	8	76
0xD	0	40-45 MHz	2.5	10	8	8	76
0xE	0	45-50 MHz	2.5	10	8	8	76

Read data capture delay is also configured when booting from QSPI. Depending on the CSEL and HPS_CLK fuse values, the Boot ROM configures the delay field of the rddatacap register in the QSPI differently. When you configure the CSEL and HPS_CLK fuses to enable the PLL, the boot ROM calibrates the interface by reading the QSPI signal for all delay values of the rddatacap register. The Boot ROM analyzes all of the delay values that return a valid signature and uses the delay value in the middle of the valid window as the value it programs into the delay field of the rddatacap register. If the PLL is not enabled, then the Boot ROM leaves the rddatacap register untouched.

A.4.4.3.3. Quad SPI Controller CSEL Settings

Table 350. QSPI Controller Clock Options Based on CSEL and HPS_CLK Fuse Settings

Note: The `oscl_clk` signal is sourced from the external oscillator input, `HPS_CLK1`.

CSEL [3:0] Fuse Values	HPS CLK Fuse Value	Required Input Clock Range	Controller clock	Controller Clock Frequency (14_main_clock)	Baud Rate Divisor	External Device Clock (Divided down reference clock)	Default Flash Read Instruction	PLL Status
0x0-0x1 and 0x3-0xF	1	60-200 MHz (Secure Bypass)	cb_intosc_hs_clk	60-200 MHz	16	3.75-12 MHz	READ	Bypassed

For more information about CSEL encodings and secure clock configuration, refer to the *SoC Security* chapter.

A.4.5. Clock Select

The boot ROM reads the clock select values to determine what frequency has been selected for the CPU clock and any interface clock during boot.

If the FPGA boot fuse is not blown, the clock select (CSEL) fuses are used to configure the main PLL and peripheral PLL. The Clock Manager samples the clock configuration on a cold and warm reset. If the `hps_clk_f` fuse is blown, the internal oscillator divided

by 2, `cb_intosc_hs_div2_clk`, is used as the boot clock. If the fuse is not blown, an external oscillator is used. During boot ROM execution, the boot code configures the device clock based on the CSEL fuse settings or software code. The `cb_intosc_hs_div2_clk` can be considered the secure reference clock option.

Note: The terms CSEL and CLKSEL are used interchangeably in Intel documentation to refer to clock select.

The CSEL settings are not used to configure the PLLs for the following conditions:

- A boot from RAM (warm reset)
- A boot from FPGA
- The clock select is set to 0x1, indicating the clocks should not be touched.

If a bypass condition is encountered, the boot ROM checks to make sure that the boot clock has a proper source according to the security level set and if it does not, the boot ROM stalls. ROM code bypasses the PLLs at warm or cold reset under the following conditions:

- The `hps_clk_f` fuse is not blown and the CSEL fuse value is 0xF. This setting is an unsecure bypass that uses the external oscillator (`HPS_CLK1`) as the clock source.
- The `hps_clk_f` fuse is not blown and the CSEL fuses values are not 0xF, 0x1 or one of the values from 0x7 to 0xE that indicates PLL use. These are mapped to unsecure bypass using the external oscillator (`HPS_CLK1`) as the clock source.
- The `hps_clk` fuse is set to secure clock, but the CSEL fuse value is not 0x2. This setting is considered secure bypass, using the internal oscillator as the clock source.

CSEL Fuse Encodings During Boot

The intent of the CSEL fuses is to give the user more control over the CPU clock in both non-secure and secure mode. For example, if you select CSEL=0x0 (the default) in non-secure mode, then the boot ROM configures all the clocks back to their default bypass (boot) mode and the MPU is clocked by the `HPS_CLK1` (10-50 MHz). However, if you have a 10 MHz external oscillator (`HPS_CLK1`) and want to operate faster, then the CSEL fuses can be programmed to 0x7 for a MPU clock of 553 MHz. Similarly, if the input clock is 25 MHz and the CSEL fuses are programmed to 0x9 then the MPU clock is 800 MHz (25 * 32). If CSEL=0xA is chosen, then the same clock gives a MPU clock of 650 MHz (25 * 26). Finally, if some set of CSEL fuses have been blown, you can return to the default bypass state (CSEL=0x0) by blowing all the fuses (CSEL=0xF).

The following tables represent the clock frequencies that are available during the boot process according the boot clock that is selected. As noted previously, when the internal secure clock, `cb_intosc_ls_clk`, is used as the boot clock, the meaning of the CSEL fuses is slightly different.

To configure the clock speeds for second-stage boot loader execution, you need to select the clock speeds in the HPS component of Platform Designer. The tables below only apply to the boot process.

**Table 351. CSEL Encodings for hps_clk_f = 0 (Non-secure Operation)**

CSEL[3:0] Fuse Value	Description	MPU Clock Value
0x0	When no fuses are blown, the boot ROM returns clocks back to their default (bypass) boot mode and the CPU is driven by the external oscillator (HPS_CLK1), which must be in the range of 10 to 50 MHz. No PLL is enabled.	External Oscillator, HPS_CLK1 (10 to 50 MHz)
0x1	All the clock codes are bypassed and the clock source is user selected.	User-selected clock source
0x2	Reserved	External Oscillator, HPS_CLK1 (10 to 50 MHz)
0x3	Reserved	External Oscillator, HPS_CLK1 (10 to 50 MHz)
0x4	Reserved	External Oscillator, HPS_CLK1 (10 to 50 MHz)
0x5	Reserved	External Oscillator, HPS_CLK1 (10 to 50 MHz)
0x6	Reserved	External Oscillator, HPS_CLK1 (10 to 50 MHz)
0x7	External oscillator input clock, HPS_CLK1, is in the range of 10 to 15 MHz	533 to 800 MHz
0x8	External oscillator input clock, HPS_CLK1, is in the range 15 to 20 MHz.	600 to 800 Mhz
0x9	External oscillator input clock, HPS_CLK1, is in the range 20 to 25 MHz.	640 to 800 Mhz
0xA	External oscillator input clock, HPS_CLK1, is in the range 25 to 30 MHz.	666 to 800 Mhz
0xB	External oscillator input clock, HPS_CLK1, is in the range 30 to 35 MHz.	685 to 800 Mhz
0xC	External oscillator input clock, HPS_CLK1, is in the range 35 to 40 MHz.	700 to 800 Mhz
0xD	External oscillator input clock, HPS_CLK1, is in the range 40 to 45 MHz.	711 to 800 Mhz
0xE	External oscillator input clock, HPS_CLK1, is in the range 45 to 50 MHz.	720 to 800 Mhz
0xF	The boot ROM returns clocks back to their default (bypass) boot mode and the CPU is driven by the external oscillator (HPS_CLK1). No PLL is enabled.	External Oscillator, HPS_CLK1 (10 to 50 MHz)

Table 352. CSEL Encodings for hps_clk_f = 1 (Secure Operation)

CSEL[3:0] Fuse Value	Description	MPU Clock Value
0x0	Bypass mode; in this mode all clocks are reset and boot mode is ensured active; cb_intosc_hs_div2_clk (cb_intosc_hs clock divided by 2) is used.	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x1	All the clock codes are bypassed and the clock is user selected.	User-selected clock source
0x2	PLL is used with the internal oscillator (30 to 100 MHz)	120 to 800 MHz
0x3	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x4	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x5	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x6	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x7	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x8	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x9	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0xA	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0xB	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0xC	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0xD	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0xE	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0xF	Bypass mode; reset all clocks and ensure boot mode is active; cb_intosc_hs_div2_clk is used.	cb_intosc_hs_div2_clk (60 to 200 MHz)

A.4.6. I/O Configuration

The flash devices needed for booting must be connected to specific I/Os. The Boot ROM configures these I/Os depending on the flash device selected by boot select setting. To configure the I/Os, the boot ROM performs pin muxing and pin configuration on these I/Os.

The boot ROM is allocated 14 dedicated HPS I/Os. There are three separate I/O tables in the boot ROM, one for each flash device.

On cold reset, the boot ROM always configures the pin muxes and pin configuration. On warm reset, the user has the capability to specify whether or not the boot ROM code configures the I/Os and pin muxes for boot pins after a warm reset. This configuration on warm reset is enabled by programming the `romcode_ctrl` register in the System Manager.

Refer to the "Boot Source I/O Pins" section for detail on mux select values.

Refer to the *Hard Processor Subsystem I/O Multiplexing* chapter for more information regarding booting I/O options and configuration.

A.4.6.1. I/O State

The state of the device I/O pins changes depending on the current operation mode of the device. The table below describes the changes in state per I/O type for each operating mode of the device.

Table 353. I/O State

I/O Type	Operation Modes from the time the FPGA is Unconfigured (POR) to User Mode				Operation Modes after the FPGA is Configured		
	Power up	HPS Boot ROM Mode	Early I/O Release Mode	User Mode	HPS Cold Reset	FPGA Partial Reconfiguration	FPGA Full Reconfiguration
Dedicated HPS I/O used during Boot	Input tri-state	Select I/O are configured by Boot ROM; unused I/O remain as input tri-state.	Select I/O are configured by software. Unused I/O remain as input tri-state.	Select I/O are configured by software. Unused I/O remain as input tri-state.	Input tri-state	Configured I/O continue to operate. Unused I/O remain as input tri-state.	Configured I/O continue to operate. Unused I/O remain as input tri-state.
HPS Shared I/O	Input tri-state ⁽⁶⁶⁾	Input tri-state unless FPGA is being configured.	Select I/O are configured by configuration bitstream. Unused I/O	Select I/O are configured by configuration bitstream. Unused I/O	Pin multiplexer is reset and thus I/O pins will be input tri-state.	Configured I/O continue to operate. Unused I/O	When full reconfiguration begins, I/O state reverts to input tristate. Once configuration is complete, unused

I/O Type	Operation Modes from the time the FPGA is Unconfigured (POR) to User Mode				Operation Modes after the FPGA is Configured		
	Power up	HPS Boot ROM Mode	Early I/O Release Mode	User Mode	HPS Cold Reset	FPGA Partial Reconfiguration	FPGA Full Reconfiguration
			remain as input tri-state.	remain as input tri-state.		remain as input tri-state.	I/O remain as input-tristate while selected I/O are configured by bitstream. <i>Note:</i> In this mode, any HPS peripheral connected to the shared I/O loses connectivity until configuration is complete.
HPS DDR I/O	Input tri-state ⁽⁶⁶⁾	Input tri-state unless FPGA is being configured.	Select I/O are configured by configuration bitstream. Unused I/O remain as input tri-state.	Select I/O are configured by configuration bitstream. Unused I/O remain as input tri-state.	Configured I/O continue to operate.	Configured I/O continue to operate. Unused I/O remain as input tri-state.	When full reconfiguration begins, I/O state reverts to input tristate. Once configuration is complete, unused I/O remain as input-tristate while selected I/O are configured by bitstream. <i>Note:</i> In this mode HPS loses connectivity to HPS DDR and may need to be reset to reboot the system.
FPGA I/O	Input tri-state ⁽⁶⁶⁾	Input tri-state unless FPGA is being configured.	Select I/O are configured by configuration bitstream. Unused I/O remain as input tri-state.	Select I/O are configured by configuration bitstream. Unused I/O remain as input tri-state.	Configured I/O continue to operate.	Configured I/O continue to operate. Unused I/O remain as input tri-state.	When full reconfiguration begins, I/O state reverts to input tristate. Once configuration is complete, unused I/O remain as input-tristate while selected I/O are configured by bitstream.

A.4.7. L4 Watchdog 0 Timer

The boot ROM enables the L4 Watchdog 0 Timer early in the boot process.

This watchdog is reserved for the boot ROM until the second-stage boot loader indicates that it has started correctly and taken control of the exception vectors. The timeout is at least one second, depending on the clock select setting. Because the watchdog is reset just before the control passes to second-stage boot loader, the second-stage boot loader must reset the watchdog when it begins execution.

The L4 watchdog 0 timer is reserved for boot ROM use. While booting, if a watchdog reset happens before software control passes to the second-stage boot loader, the boot ROM code attempts to load the last valid second-stage boot loader image, identified by the `initswlastld` register in the System Manager.

If the watchdog reset happens after the second-stage boot loader has started executing but before it writes a valid value to `initswstate` register, the boot ROM increments `initswlastld` and attempts to load that image. If the watchdog reset happens after the second-stage boot loader writes a valid value to `initswstate` register, the boot ROM code attempts to load the image indicated by `initswlastld` register.

A.4.8. Second-Stage Boot Loader

The function of the second-stage boot loader is user-defined. The Intel-provided second-stage boot loader is a combination of initialization, configuration and U-Boot code and contains features such as:

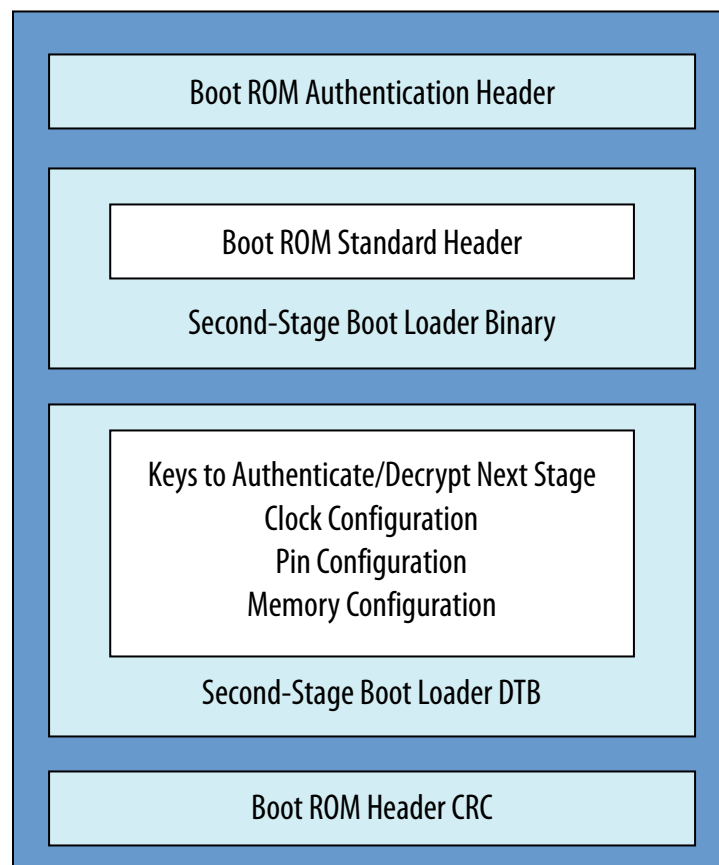

- SD/MMC controller driver
- QSPI controller driver
- Ethernet driver plus protocol support
- Drivers for system-level IP, such as Clock Manager, System Manager, and FPGA Manager
- Cache memory drivers
- UART, timer and watchdog drivers
- FAT file system support
- Flat Image Tree (FIT) image processing
- U-Boot console support including basic essential debug commands
- Cryptographic library
- Flattened device tree (FDT) processing library
- System and memory firewall configuration
- Initialization code for the HPS and FPGA I/O and the interface that loads the next stage of software

If a secure boot is required, the second-stage boot loader can be used to increase the level of security and to authenticate and initiate decryption of the next boot image if necessary.

If the hard memory controller I/O in the SoC device have been configured through the FPGA or HPS and the SDRAM firewall access has been lowered, the second-stage boot loader can be used to load the next stage of the boot software into SDRAM. The maximum length for a second-stage boot loader to fit into on-chip RAM is 208 KB with authentication and 224 KB without authentication. A typical next software stage is loading the application OS software. The second-stage boot loader is allowed to load the next stage boot software from any device available to the HPS. Typical sources include the same flash device that contains the second stage boot loader, a different flash device, or a communication interface such as an EMAC.

If the second-stage boot loader must be authenticated, it must store a public key. Below is a figure which depicts the second-stage boot loader image presented to the boot ROM, during a secure, authenticated boot.

Figure 204. High-Level Diagram of Second-Stage Boot Loader Image

A.4.9. Secure Boot

The boot ROM supports both non-secure and secure boot.

Secure boot allows the HPS to release from reset into a known state and then validate the authenticity and integrity of the second-stage boot loader code prior to executing it. Secure boot can ensure that only authorized code is executed on the system. In

addition, the system has the option to configure the FPGA from the HPS, which provides a secure boot mechanism for the FPGA portion of the SoC. In this mode, the HPS boot code can authenticate the FPGA POB prior to loading it.

The boot ROM determines the security level based on user fuse values that are stored in the Security Manager during initialization. The second-stage boot loader may provide a security header to indicate authentication or decryption for the image. Based on the merged data from security manager and the security header, the boot ROM can load the following images:

- Clear text: No authentication or decryption is required
- Secure, Authenticated - Authentication but no decryption is required on the image
- Secure, Encrypted - Decryption, but no authentication is required. During the decryption process, the boot ROM looks for an encrypted image on the flash device and decrypts it into the on-chip RAM
- Full Secure - Both authentication and decryption are required

The authentication process is independent of the decryption process. However, if authentication and decryption are both required, authentication is done before the decryption process.

For more information regarding Secure Boot, please refer to the *SoC Security* Chapter.

A.5. Boot ROM Flow

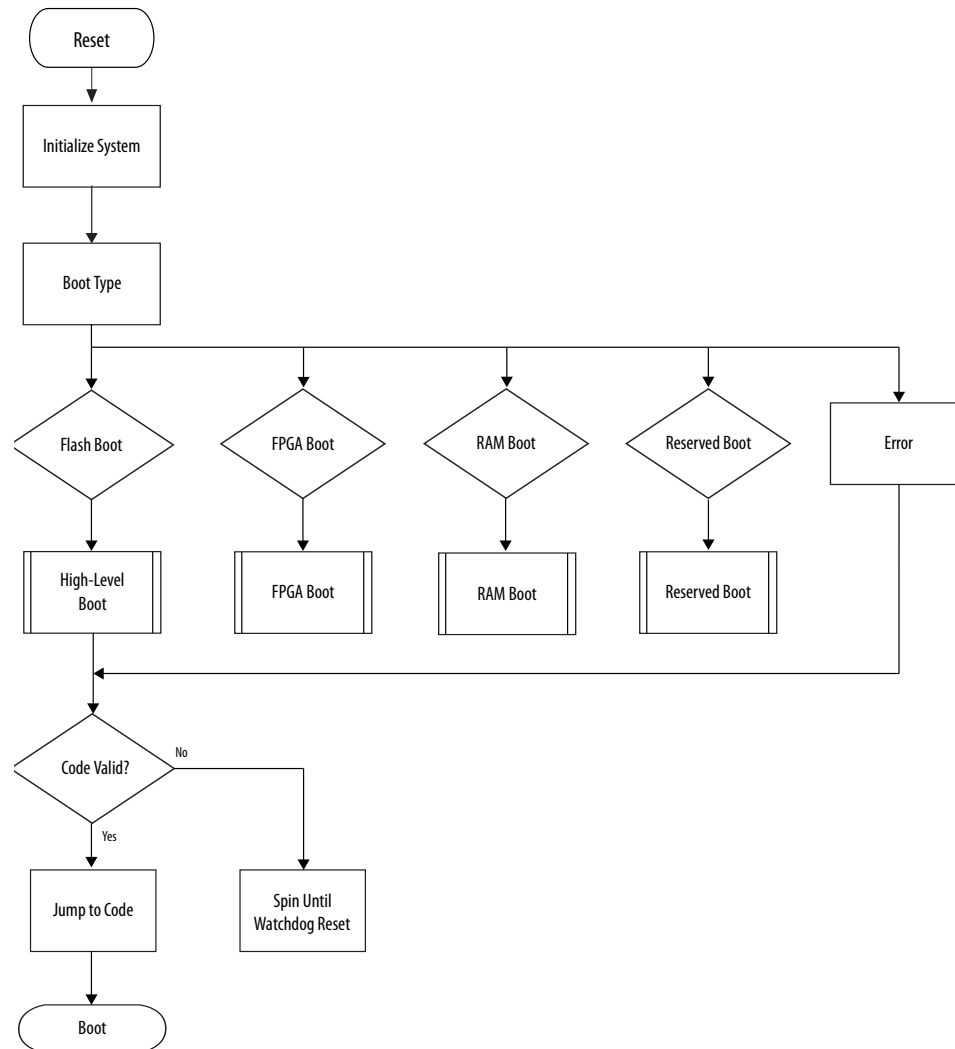

On a cold reset, the HPS boot process starts when CPU0 is released from reset (for example, on a power up) and executes code in the internal boot ROM at the reset exception address, 0x00000000. The boot ROM code brings the HPS out of reset and into a known state. After boot ROM code is exited, control passes to the next stage of the boot software, referred to as the second-stage boot loader. The second-stage boot loader can be customized and is typically stored external to the HPS in a nonvolatile flash-based memory or in on-chip RAM within the FPGA. The second-stage boot loader can then load an OS, BareMetal application or potentially a third-stage boot loader.

This section describes the software flow from reset until the boot ROM code passes software control to the second-stage boot loader.

The code starts, initializes the system and then depending on the type of boot requested, it may attempt to load the code into the on-chip RAM. An on-chip RAM boot can only occur on a warm reset. Warm boot from on-chip RAM has the highest priority to execute if the `warmram_*` registers in the system manager has been configured to support booting from on-chip RAM on a warm reset. If the `warmram_enable` register in the system manager is set to 0xAE9EFEB, then the boot ROM code attempts to boot from on-chip RAM on a warm reset and the boot ROM does not configure boot I/Os, pin-muxes or clocks. The `warmram_datastart` and `warmram_length` registers in System Manager allow you to program the offset of the beginning of code and the length of the region of on-chip RAM for CRC validation. If the `warmram_length` register is clear, then the boot ROM does not perform a CRC calculation in the on-chip RAM. If the `warmram_length` register is non-zero, then CRC checking is performed. If CRC checking is successful, then the boot ROM jumps to

global address programmed in the `warmram_execution` register. If for three subsequent load attempts, the boot ROM fails to find code or the CRC check fails, the boot ROM spins, waiting for a watchdog reset.

Figure 205. Main Boot ROM Flow

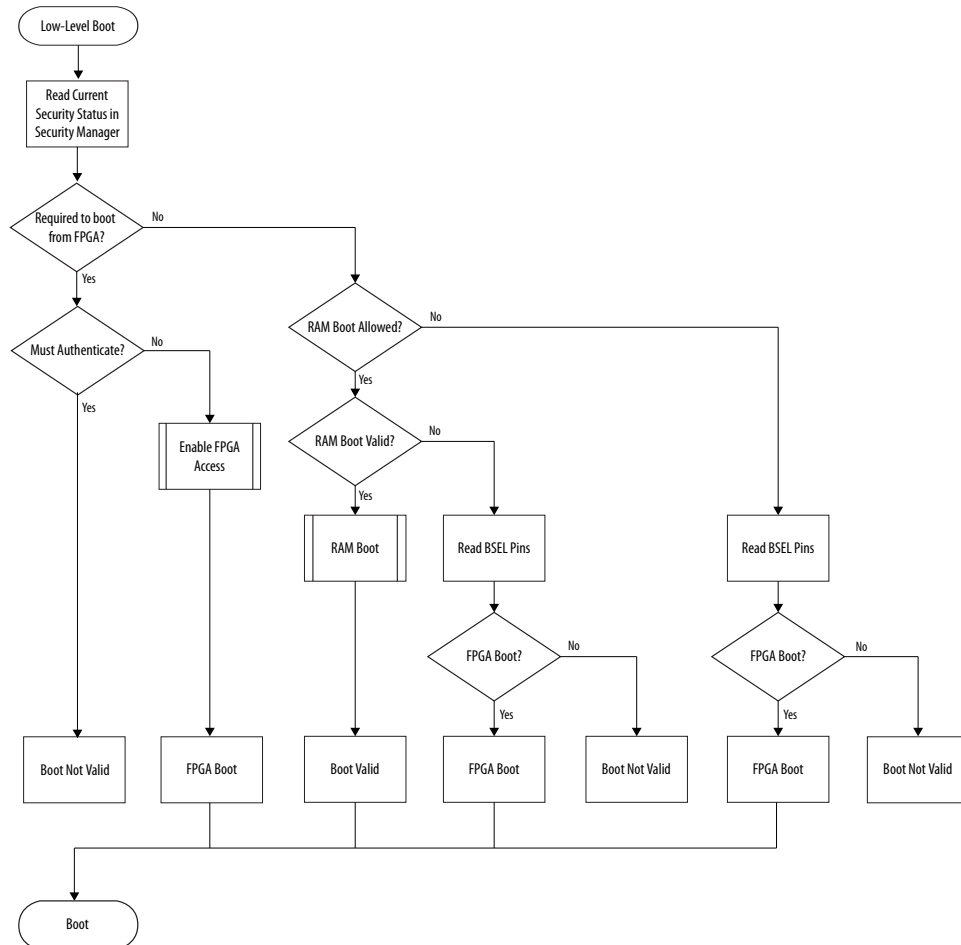

The boot ROM always executes on CPU0. CPU1 is always held in reset while the main boot ROM code is executing and is only released when required by system software.

As part of determining the boot type, the boot ROM executes a low-level boot flow. The boot ROM code reads the security fuse to determine if the source of the second-stage boot is forced to be the FPGA. If a non-authenticated FPGA boot or a non-CRC on-chip RAM boot is requested or the boot is invalid, it is processed within the low-level boot flow. All other boot types are processed within the high-level boot flow.

Figure 206. Low-Level Boot Flow

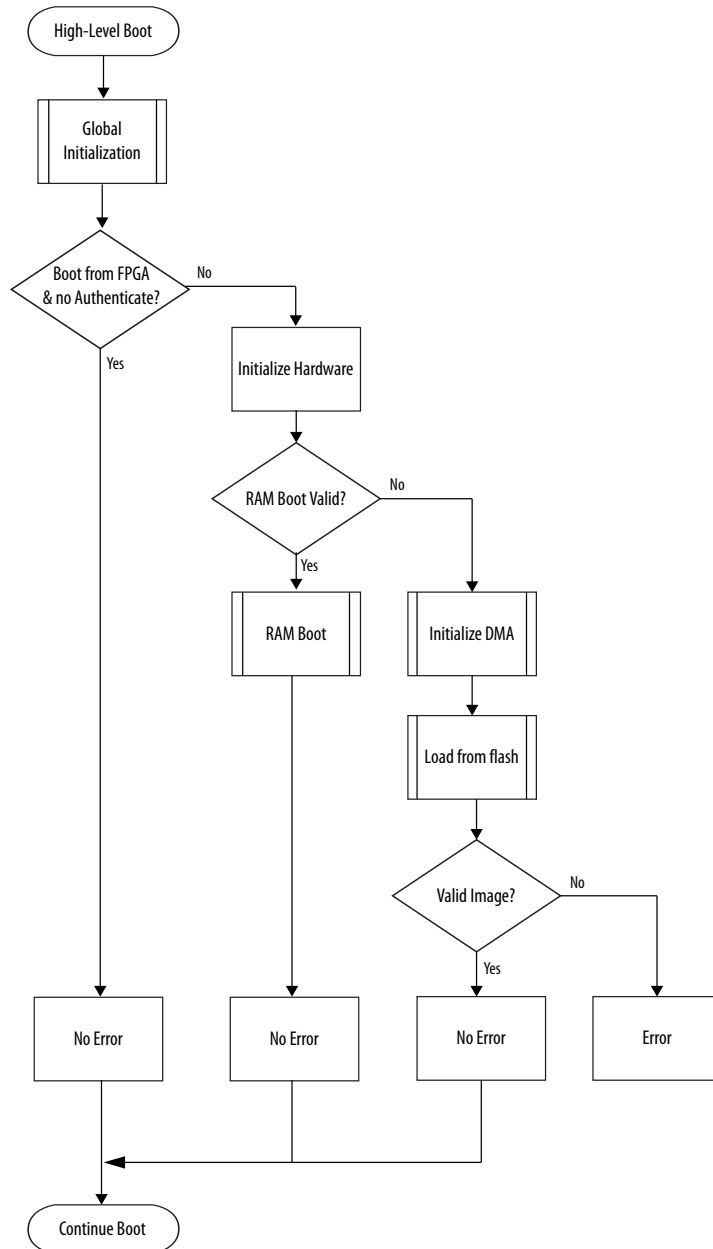

During the low-level portion of the boot ROM flow, the boot ROM reads the security fuses to determine if an FPGA-only boot is required. If so, then the boot ROM must also determine if the fuses indicate that authentication of the POF is needed. If no authentication is required, then a standard FPGA configuration occurs.

If an FPGA-only boot is not required, then the boot ROM checks if an on-chip RAM boot is allowed. If it is, then the boot ROM checks to see if the code is valid. If the code is invalid, the boot ROM reads the BSEL pins to determine if it indicated an FPGA boot.

If the secure fuses indicate that authentication is required for the boot image, then a high-level boot (executed in C code) must be performed.

Figure 207. High-Level Boot Flow

During the boot process, authentication and decryption can be performed on the boot image. Authentication is independent of decryption; however, if both authentication and decryption are required, then authentication always occurs first. If an authenticated boot is required, then the boot ROM must have a root key to start the authentication process. This key can be implemented in the user fuses, in the FPGA logic elements or as part of the second-stage boot image header. The device configuration fuses determine the source of the key.

During a cold boot from flash memory, the boot ROM code attempts to load the first second-stage boot loader image from flash memory to on-chip RAM and pass control to the second-stage boot loader. If this initial image is invalid, the boot ROM code indexes the `romcode_initswlastld` register and attempts to load the next stored image. The boot ROM will attempt three subsequent loads after the initial one. If there is still no valid image found after the subsequent loads, the boot ROM code checks the FPGA portion of the device for a fallback image.

Note: During the boot process, the boot ROM enables all of the caches (L1 data and instruction caches and L2 cache). If the second-stage boot loader is not loaded from a boot flash device (SD/MMC, QSPI, NAND) properly, the caches may be left on when the boot ROM checks the FPGA portion the device for a fallback image. This situation can lead to issues of coherency when loading code, so caches must be flushed and disabled in the fallback image.

If the warm RAM boot has failed or if a cold reset has occurred, then the boot ROM reads the BSEL value in the `bootinfo` register of the System Manager. If the FPGA is selected as the boot source, then the boot ROM code attempts to execute code at address 0xC0000000 across the HPS-to-FPGA bridge (offset 0x00000000 from bridge). No error conditions are generated if the FPGA does not initialize properly and the watchdog is not enabled for time-out. Instead, the boot ROM continues to wait until the FPGA is available.

If the BSEL bits indicate a boot from external flash, then the boot ROM code attempts to load an image from a flash device into the on-chip RAM, verify and execute it. If the BSEL is invalid or the boot ROM code cannot find a valid image in the flash, then the boot ROM code checks if there is a fallback image in the FPGA. If there is, then the boot ROM executes the fallback image. If there is no fallback image then the boot ROM performs a post-mortem dump of information into the on-chip RAM and awaits a reset.

Note: The acronyms BSEL and BOOTSEL are used interchangeably to define the boot select pins.

The boot ROM code verifies the second-stage boot loader in several ways to ensure a corrupted image is not executed. The first test is of the image header, which identifies the magic number, version, block length, and CRC of the image that protects the block. If any of these are invalid, an error occurs.

A.6. Second-Stage Boot Flow

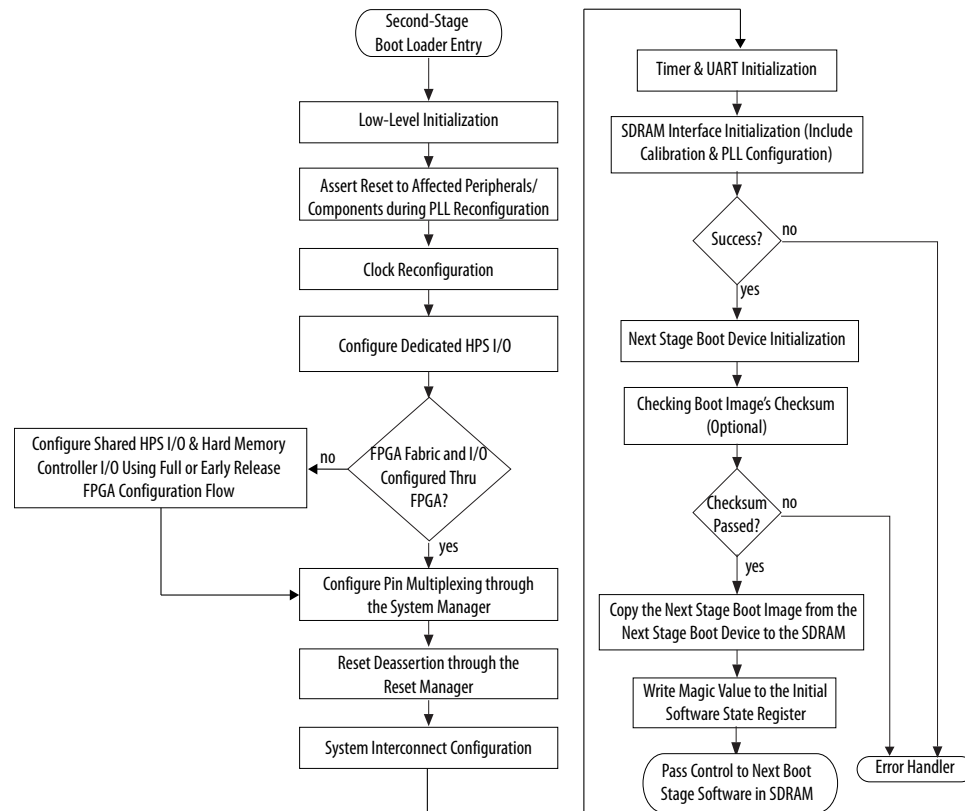

The second stage boot loader has the capability of supporting the following types of boot:

- Non-secure clear text boot
- Secure boot with:
 - Authentication only (also called verified boot)
 - Decryption only
 - Authentication and decryption

A.6.1. Typical Boot Flow (Non-Secure)

A non-secure second-stage boot process typically follows a flow as in the following figure.

Figure 208. Typical Second-Stage Boot Loader Flow (Non-Secure)

Low-level initialization steps include reconfiguring or disabling the L4 watchdog 0 timer, invalidating the instruction cache and branch predictor, remapping the on-chip RAM to the lowest memory region, and setting up the data area.

Upon entering the second-stage boot loader, the L4 watchdog 0 timer is active. The second stage boot loader can disable, reconfigure, or leave the watchdog timer unchanged. Once enabled after reset, the watchdog timer cannot be disabled, only paused or reset.

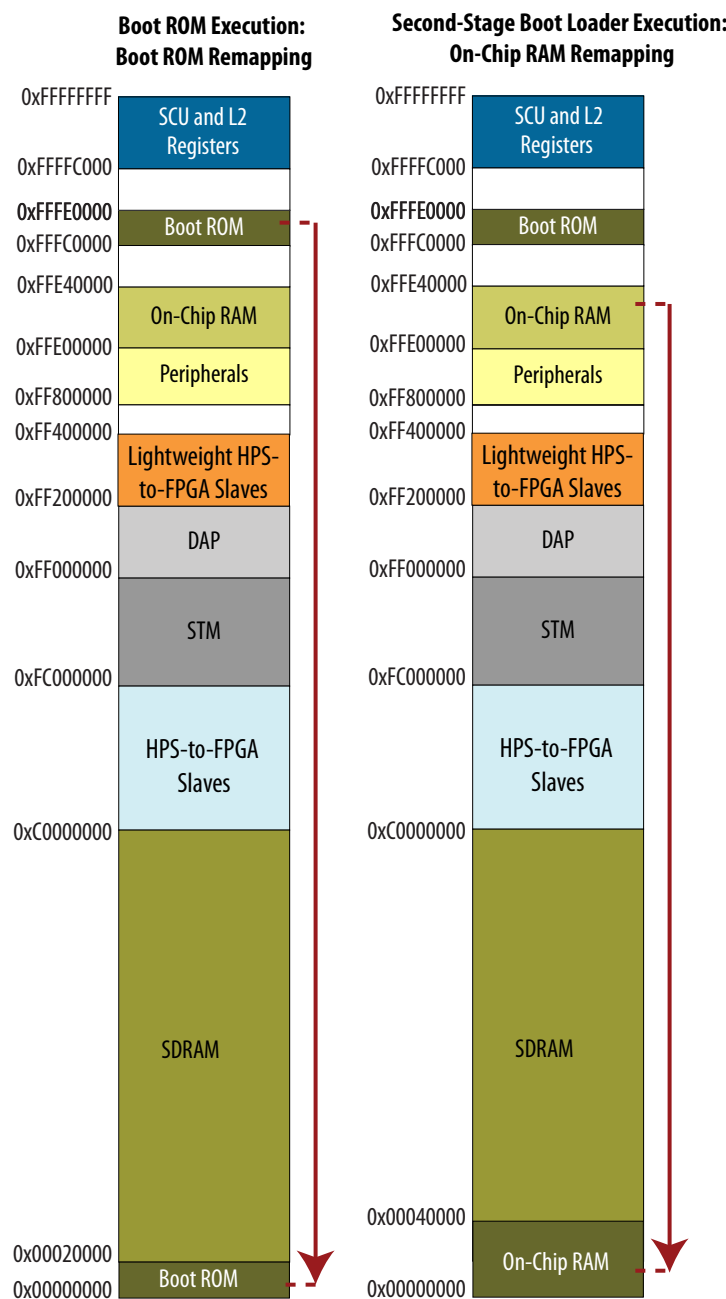

The instruction cache and branch predictor, which were previously enabled by the boot ROM code, must be invalidated. If the second-stage boot loader enables and uses the data cache, it must initialize all levels of the data cache before enabling.

The second-stage boot loader must remap the exception vector table because the exception vectors are still pointing to the exception handler in the boot ROM when it starts executing. By setting the system interconnect remap bit 0 to one, the on-chip RAM mirrors to the lowest region of the memory map. After this remap, the exception vectors use the exception handlers in the boot loader image.

The figure below shows the memory map before and after remap. The first mapping depicts boot ROM execution. The second mapping shows the remap of the on-chip RAM when the remap bit is set during second-stage boot loader execution.

Figure 209. Remapping the On-Chip RAM

The second-stage boot loader can reconfigure all HPS clocks. During clock reconfiguration, the boot loader asserts reset to the peripherals in the HPS affected by the clock changes.

The I/O assignments for the HPS are configured as part of the IOCSR configuration in the second-stage boot loader. Effectively, a bitstream containing the I/O assignments is sent to the device as part of the initialization code in the second-stage boot loader. If the FPGA fabric and I/O have not yet been configured through the FPGA and the HPS needs to access SDRAM, you should program the HPS to use the full or early I/O release configuration method to configure the shared and hard memory controller I/O. Refer to "FPGA Configuration" section of the "Booting and Configuration" appendix in the *Arria 10 Hard Processor System Technical Reference Manual* for details on full and early I/O release configuration.

The second-stage boot loader looks for a valid next-stage boot image in the next-stage boot device by checking the boot image validation data and checksum in the mirror image. Once validated, the second-stage boot loader copies the next-stage boot image (OS or application image) from the next-stage boot device to the SDRAM.

Before software passes control to the next-stage boot software, the second-stage boot loader can write a valid value (0x49535756) to the `romcode_initswstate` register in the System Manager. This value indicates that there is a valid boot image in the on-chip RAM. The `romcode_initiswlastld` register holds the index of the last second-stage boot loader software image loaded by the Boot ROM from the boot device. When a warm reset occurs, the Boot ROM loads the image indicated by the `romcode_initiswlastld` register if the BSEL value is the same as the last boot.

A.6.2. Secure Boot Flow

The main purpose of secure boot is to pass the chain of trust to the subsequent boot software. During a secure boot, the second-stage boot loader may authenticate or decrypt the subsequent boot image, depending on the current state registers in the

Security Manager. In addition, the second-stage boot loader must ensure that the subsequent boot image is executed from secure memory such as on-chip RAM. The second-stage boot loader fits into the chain of trust as such:

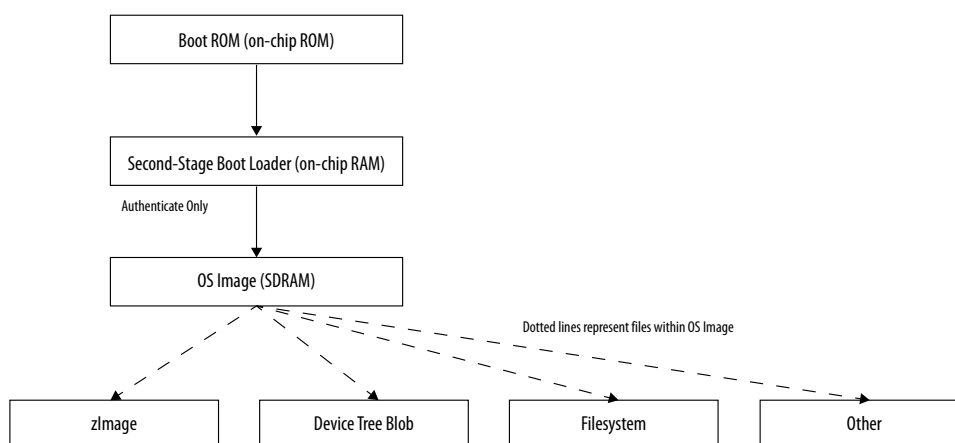

Figure 210. Secure Boot Flow

The micro OS provides secure APIs to allow the application in the normal world OS to establish trusted services.

During a verified boot, the second-stage boot loader only authenticates the OS image and other images required by the OS. A flow for a verified boot is shown below.

Figure 211. Verified (Authenticated) Boot Flow

For both the secure and verified boot, the subsequent boot image must be executed in on-chip RAM while the second-stage boot loader is still executing from on-chip RAM. In order to accommodate this requirement, the authentication and decryption process might follow the following steps depicted in the next three diagrams, depending on the type of secure boot chosen.

Figure 212. Second-Stage Boot Loader Authentication Process

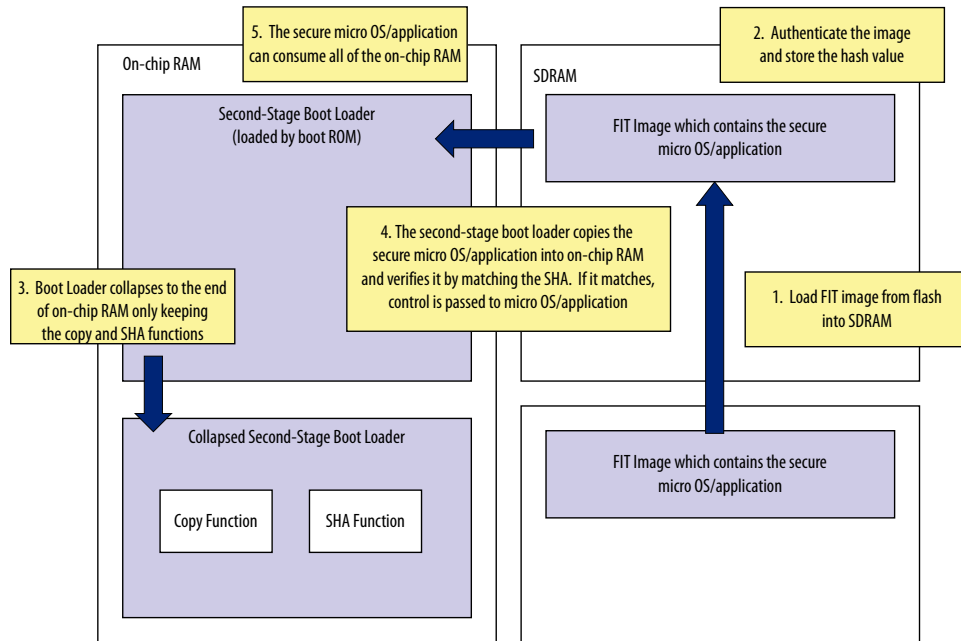

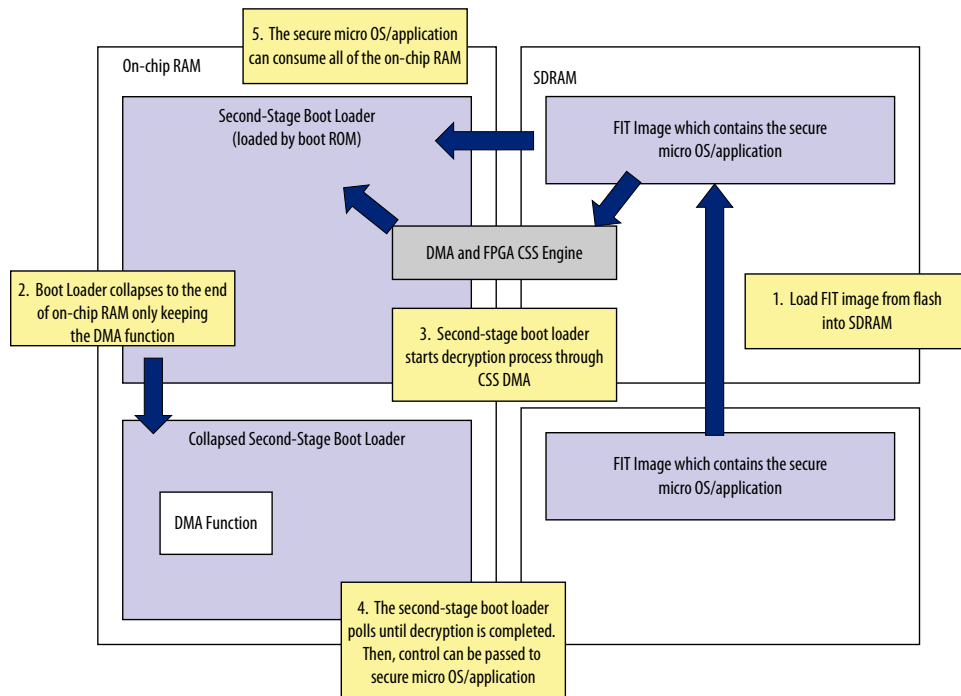

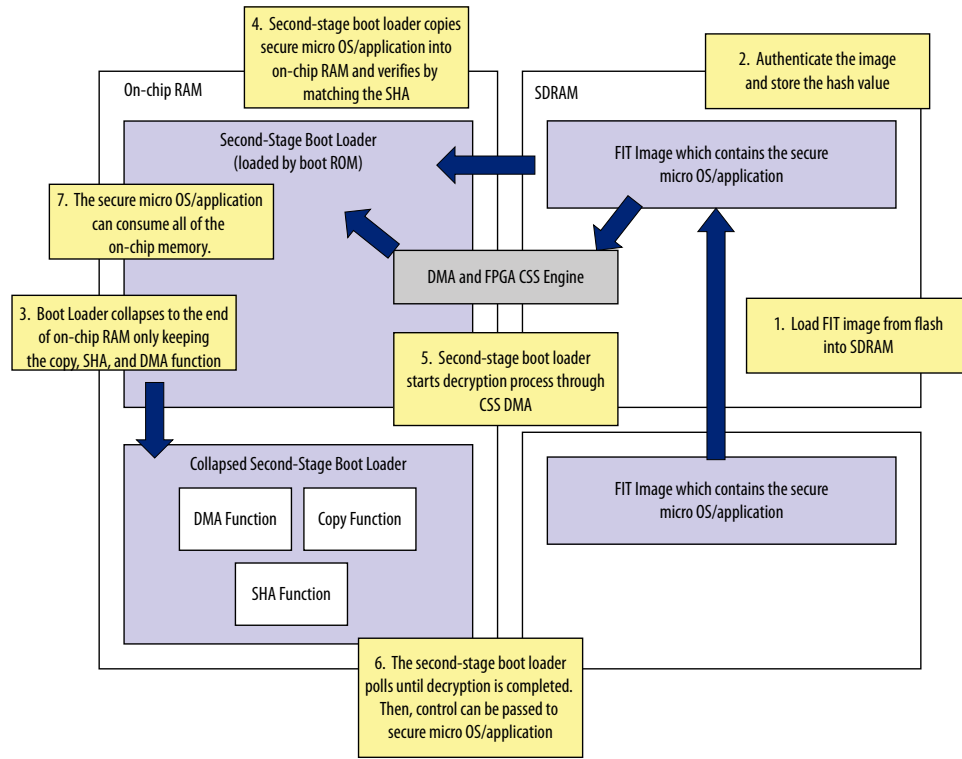

Figure 213. Second-Stage Boot Loader Decryption Process

Decryption is optional and is not required for secure boot. Upon entry into the second-stage boot loader, the CSS engine is enabled. The second-stage boot loader decrypts the subsequent boot image and disables the CSS engine upon exit.

Figure 214. Second-Stage Boot Loader Authentication and Decryption Process

A.6.3. HPS State on Entry to the Second-Stage Boot Loader

When the boot ROM code is ready to pass control to the second-stage boot loader, the processor (CPU0) is in the following state:

- Instruction cache is enabled
- Branch predictor is enabled
- Data cache is disabled
- MMU is disabled
- Floating point unit is enabled
- NEON vector unit is enabled
- Processor is in Arm secure supervisor mode

The boot ROM code sets the Arm Cortex-A9 MPCore registers to the following values:

- r0—contains the pointer to the shared memory block, which is used to pass information from the boot ROM code to the second-stage boot loader. The shared memory block is located in the top 4 KB of on-chip RAM.
- r1—contains the length of the shared memory.
- r2—unused and set to 0x0.
- r3—points to the version block.

All other MPCore registers are undefined.

Note: When booting CPU0 using the FPGA boot, or when booting CPU1 using any boot source, all MPCore registers, caches, the MMU, the floating point unit, and the NEON vector unit are undefined. HPS subsystems and the PLLs are undefined.

When the boot ROM code passes control to the second-stage boot loader, the following conditions also exist:

- CPU0 is in a secure system mode.
- The boot ROM is still mapped to address 0x0.
- The L4 watchdog 0 timer is active and has been toggled.
- The shared L2 cache is left in an uninitialized state.

The boot ROM also saves the state of the reset cause in the `stat` register of the Reset Manager, and this information is available for the Second-Stage Boot Loader to read.

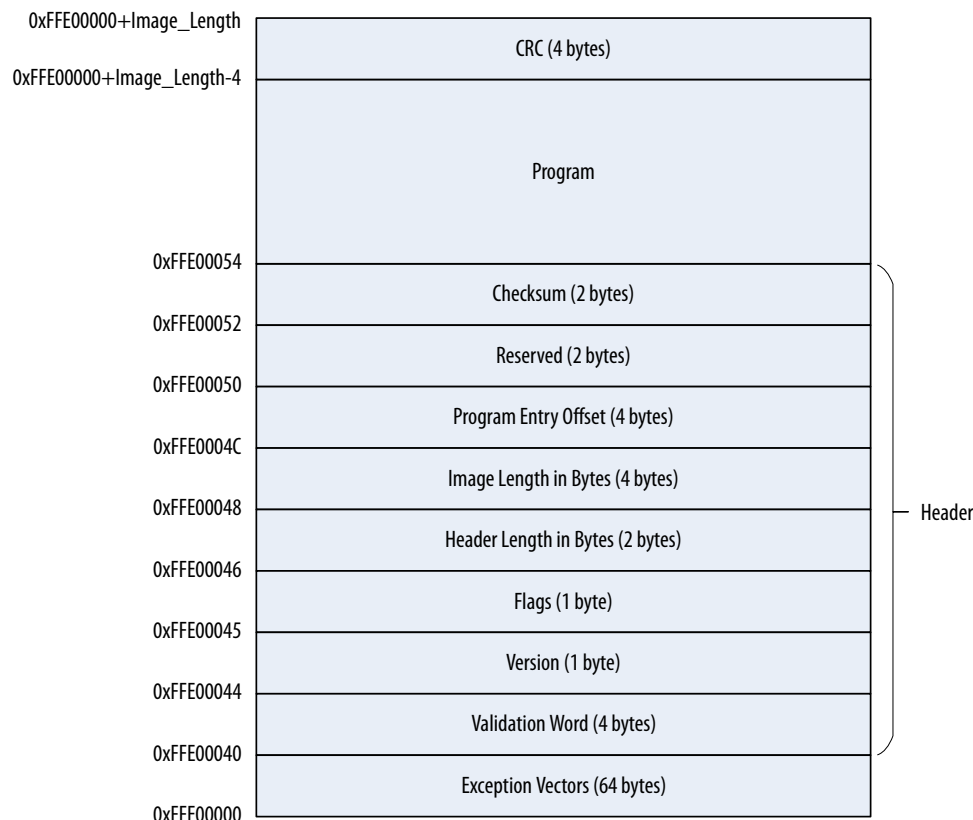

A.6.4. Loading the Second-Stage Boot Loader Image

The boot ROM code loads the image from flash memory into the on-chip RAM and passes control to the second-stage boot loader. The boot ROM code checks for a valid image by verifying the header and cyclic redundancy check (CRC) in the second-stage boot loader image.

The maximum second-stage boot loader size is 208 KB with authentication and 224 KB without. This size is limited by the on-chip RAM size of 256 KB, where 48KB or 32 KB is reserved as a workspace for the boot ROM data and stack depending on whether authentication is enabled or not. The second-stage boot loader can use this reserved region (for its stack and data, for example) after the boot ROM code passes control to the second-stage boot loader. This reserved region is overwritten by the boot ROM code on a subsequent reset. The following figure shows the second-stage boot loader image layout in the on-chip RAM after being loaded from the boot ROM.

Figure 215. Second-Stage Boot Loader Image

- **Exception vectors**—Exception vectors are located at the start of the on-chip RAM. Typically, the second-stage boot loader remaps the lowest region of the memory map to the on-chip RAM (from the boot ROM) to create easier access to the exception vectors.
- **Header**—contains information such as validation word, version, flags, program length, security settings, and checksum for the boot ROM code to validate the second-stage boot loader image before passing control to the second-stage boot loader.
- **Version**—This byte describes the version and layout of the program header. This value must be 0x1.
- **Flags**— Not used.
- **Header length**— The length of the header in bytes.
- **Image length** — The total length of the image (including the exception vectors and the CRC field)
- **Program entry offset**— The boot ROM jumps to this offset. The offset value is in bytes from the start of the program header (0xFFE00040).
- **Reserved** —Not used. Must be set to 0x0.

- **Checksum**— A simple checksum of all the bytes from 0xFFE00040 to 0xFFE00051, inclusive
- **Program** — Program contents which typically includes U-Boot binary and U-Boot Device Tree Blob (DTB).
- **CRC**—There is a CRC value for the entire image. The CRC consists of data located from address 0xFFFE0000 to 0xFFFE0000+(Image Length)–0x0004. The polynomial used to validate the image is:
$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

There is no reflection of the bits. The initial value of the remainder is 0xFFFFFFFF and the final value is XORed with 0xFFFFFFFF.

A.7. FPGA Configuration

You can configure the FPGA portion of the SoC device with non-HPS sources or by utilizing the HPS.

When the HPS handles the initial FPGA configuration, software executing on the HPS writes the configuration image to the FPGA Manager in the HPS. Software can control the configuration process and monitor the FPGA status by accessing the control and status register (CSR) interface in the FPGA Manager.

For the HPS to configure the FPGA, the mode select (MSEL) pins must be set to passive mode (fast or slow). The following table shows the pin encodings for MSEL[2:0] that are available to the HPS. Refer to the *Configuration, Design Security, and Remote System Upgrades in Arria 10 Devices* document for a comprehensive list of MSEL encodings.

Table 354. MSEL Pin Settings Options for FPGA Configuration through HPS

Configuration Scheme allowed through HPS	Power-On Reset (POR) Delay	Valid MSEL[2:0]
FPP (x16, and x32)	Fast	000
	Standard	001

Note: You must also select the configuration scheme in the **Configuration** page of the **Device and Pin Options** dialog box in the Intel Quartus Prime software. Based on your selection, the option bit in the programming file is set accordingly.

There are two types of initial FPGA configuration flows you can choose from when using the HPS to configure the FPGA.

- Full FPGA configuration flow: In this flow, the FPGA fabric, the shared I/O and hard memory controller I/O are configured. After full configuration is complete, the hard memory controller I/O, shared I/O and FPGA I/O are available to the HPS.
- Early I/O release configuration flow: In this flow, all I/O are configured and the HPS shared I/O and hard memory controller I/O are released so that the HPS has immediate access to them. At a later time, the FPGA fabric is configured and the FPGA I/O are released and available to the user design.

Note: If you are using the early I/O release configuration flow, you cannot initially use SmartVID to power your device. Instead, you can use a fixed power supply until after the FPGA is configured. When the FPGA is configured, you can then enable SmartVID.

Note: It is important that the HPS is not held in cold or warm reset indefinitely, otherwise the CSS will not be accessible to FPGA configuration sources.

A.7.1. Full FPGA Configuration Flow Through HPS

Figure 216. Full FPGA Configuration Flow Through HPS

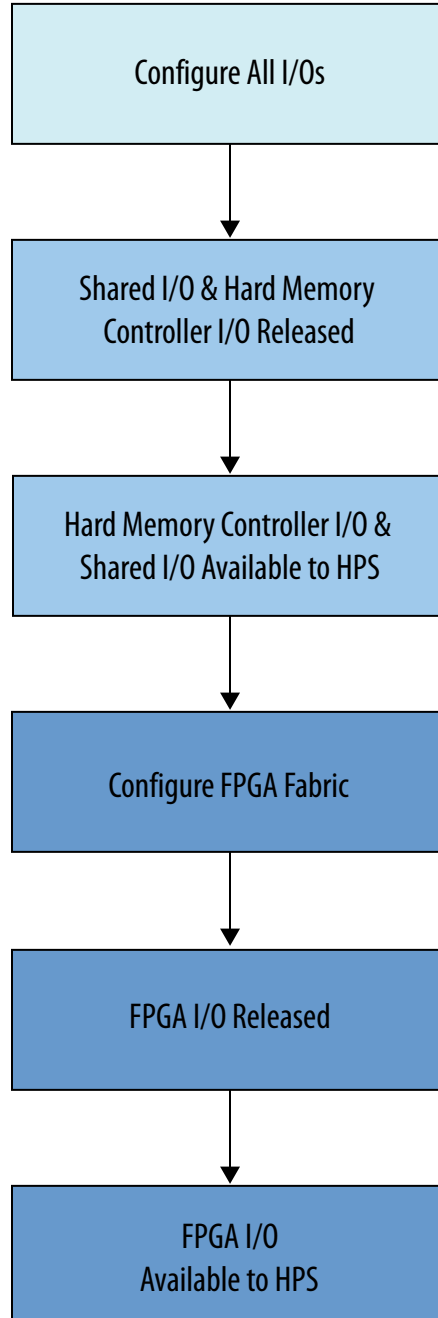

The FPGA fabric and the all I/Os are configured first and then all the I/O are released for use by the HPS.

A.7.2. Early I/O Release FPGA Configuration Flow Through HPS

Figure 217. Early I/O Release FPGA Configuration Flow Through HPS

The I/Os are configured and the shared and hard memory controller I/Os are released so that the HPS has immediate access to them. The FPGA fabric configuration follows at a later time.

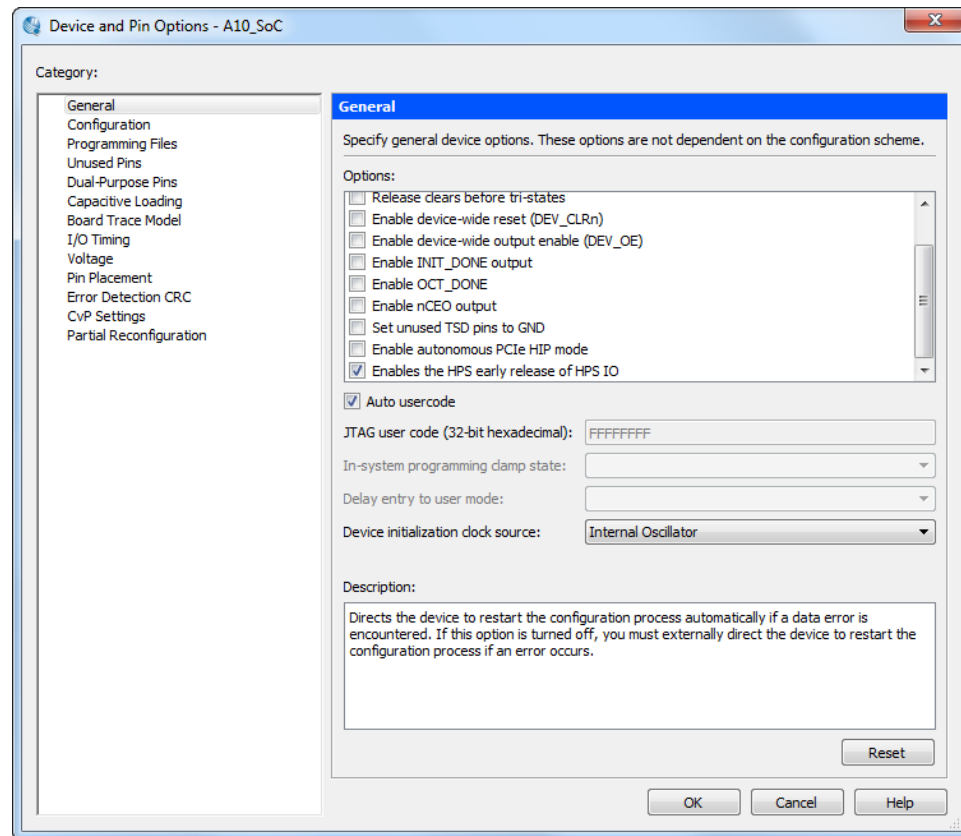

Note: The FPGA fabric is not required to be programmed immediately after the first I/O configuration. You can also program the I/Os, re-program the I/Os and then program the FPGA fabric as long as the early I/O release configuration option is enabled in each I/O configuration file.

Note: If you are using the early I/O release configuration flow, you cannot initially use SmartVID to power your device. Instead, you can use a fixed power supply until after the FPGA is configured. When the FPGA is configured, you can then enable SmartVID.

You can enable early I/O configuration in Intel Quartus Prime:

1. Click on the the **Assignments** menu and select **Device**.
2. When the **Device settings** window opens, click the **Device and Pin Options** button.
3. In the **General** category, click on the option labeled "Enables the HPS early release of HPS IO".

Figure 218. Intel Quartus Prime Early I/O Release Setting

A.7.2.1. Handling an FPGA Configuration Failure after Early I/O Release

If an FPGA configuration failure occurs after early I/O release, the HPS shared I/O and hard memory controller I/O enter input tri-state mode. In this situation, any accesses to peripherals or memory interfacing these I/O will fail. HPS dedicated I/O are not affected by FPGA configuration failures.

If you are using early I/O release and issuing an HPS-initiated FPGA configuration afterward, you must ensure that your software routine includes a way to avoid FPGA configuration failure or a recovery mechanism that does not rely on the HPS shared I/O or hard memory controller I/O.

You must implement one of the following solutions in software.

- To prevent FPGA configuration failure, load the FPGA core configuration file into SDRAM and perform an FPGA integrity check before initiating configuration. For example, you can run a custom integrity check, such as a CRC, on the `.rbf` file to validate that there are no errors in the file. Intel also recommends that you enable ECC capabilities to avoid bit-stream corruption issues.
- To recover from an FPGA configuration failure, execute the HPS-initiated configuration from on-chip RAM. If the HPS is executing entirely from on-chip RAM, you can recover your application by reconfiguring the peripheral `.rbf` file to reenable the HPS shared I/O and hard memory controller I/O. After these I/O are recovered, your application can either attempt to configure the same FPGA image that caused the original failure or use a fallback core `.rbf` file to prevent the same failure from occurring repeatedly.

Note: If you are using full FPGA configuration, you do not need to make any of the adjustments listed above. For full FPGA configuration, the `.rbf` file contains both the core and peripheral configuration and your application can only access the HPS I/O after the device is successfully configured.

A.7.3. Arria 10 SoC FPGA Configuration Sequence Through FPGA Manager

The FPGA Manager in the HPS has the capability to execute an initial FPGA configuration using the full or early I/O release flow.

The steps below detail the programming of the FPGA Manager to initiate configuration.

1. Read the `f2s_msel[2:0]` field in the `imgcfg_stat` register to verify that the configuration mode is the passive fast (000) or passive slow (001).
2. Write the `cfgwidth` bit of the `imgcfg_ctrl_02` register in the FPGA manager to match the characteristics of the configuration image. For full, standard configuration, the `cfgwidth` bit must be set to 1. You can only initiate a full, standard configuration in 32-bit passive parallel mode.
3. Configure the `cdratio` field. The `cdratio` is a function of the datawidth and whether the POF is encrypted or compressed. This information should be provided through the Intel Quartus Prime configuration. For example, if `cfgwidth` is 32-bits and the POF is compressed, you must program the `cdratio` field to 0x8. If the POF is encrypted, then program the `cdratio` to 0x4.
4. Ensure there are no other external devices interfering with the FPGA programming. Poll the `f2s_nconfig_pin` and `f2s_nstatus_pin` bits from the `imgcfg_stat` register until they are both 1.
5. Program the following bits to deassert signal drives from the HPS before overriding the signals.
 - `s2f_nce` = 1 in the `imgcfg_ctrl_01` register
 - `s2f_pr_request` = 0 in the `imgcfg_ctrl_01` register
 - `en_cfg_ctrl` = 0 in the `imgcfg_ctrl_02` register

- `s2_nconfig = 1` in the `imgcfg_ctrl_00` register
- `s2f_nstatus_oe = 0` in the `imgcfg_ctrl_00` register
- `s2f_condone_oe = 0` in the `imgcfg_ctrl_00` register
- 6. Enable overrides for the DATA, DCLK, nCE, PR_REQUEST and nCONFIG signals.
 - `s2f_nenable_config = 0` in the `imgcfg_ctrl_01` register
 - `s2f_nenable_nconfig = 0` in the `imgcfg_ctrl_00` register
- 7. Disable overrides for the nSTATUS and CONF_DONE signals.
 - `s2f_nenable_nstatus = 1` in the `imgcfg_ctrl_00` register
 - `s2f_nenable_condone = 1` in the `imgcfg_ctrl_00` register
- 8. Assert the chip select signal.
 - `s2f_nce=0` in the `imgcfg_ctrl_01` register
- 9. Repeat step 4. Ensure there are no other external devices interfering with the FPGA programming. Poll the `f2s_nconfig_pin` and `f2s_nstatus_pin` bits from the `imgcfg_stat` register until they are both 1.
- 10. Reset the configuration.
 - a. Write a 0 to the `s2f_nconfig` bit in the `imgcfg_ctrl_00` register.
 - b. Poll the `f2s_nstatus_pin` bit in the `imgcfg_stat` register until it is clear.
 - c. Write a 1 to the `s2f_nconfig` bit in the `imgcfg_ctrl_00` register.
 - d. Poll the `f2s_nstatus_pin` bit in the `imgcfg_stat` register until it is set. In addition, read and confirm the `f2s_condone_pin` is clear and the `f2s_condone_oe` is set in the `imgcfg_stat` register.
- 11. Enable DCLK and the DATA path by setting the `en_cfg_ctrl` bit in the `imgcfg_ctrl_02` register.
- 12. Write the bitstream data to the `img_data_w` register. When sending the bitstream data, you can periodically read and confirm that the `f2s_nstatus_pin` bit is set in the `imgcfg_stat` register. If it is not set, configuration has failed and you must restart with step 1.
- 13. When you have completed writing the data, continuously poll the `f2s_condone_pin` bit in the `imgcfg_stat` register until it reads as 1. When this bit is 1, it indicates configuration has completed. If the routine times out with `f2s_nstatus_pin=0`, configuration has failed and you must restart from step 1.
- 14. Write the `dclkcnt` register with 0xF and continuously poll until the `dclkcntstat` register reads as 0x0. A minimum of 2 DCLK cycles are needed after the CONFIG_DONE assertion for initialization to start.
- 15. Wait for the initialization sequence to complete. Poll the `f2s_usermode` bit in the `imgcfg_stat` register until it reads as 1.
- 16. Disable the DATA path and DCLK by clearing the `en_cfg_ctrl` bit in the `imgcfg_ctrl_02` register.
- 17. Disable the chip select. Set the `s2f_nce` bit in the `imgcfg_ctrl_01` register.
- 18. Disable overrides to the nCONFIG, DATA and DCLK signals.
 - `s2f_nenable_config=1`

- s2f_nenable_nconfig=1
19. Check that user mode is enabled and the configuration is done by checking that the bits below have the following values:
- f2s_usermode=1 in the imgcfg_stat register
 - f2s_nstatus_pin=1 in the imgcfg_stat register
 - f2s_condone_pin=1 in the imgcfg_stat register

A.8. FPGA Reconfiguration

The FPGA Manager also supports FPGA reconfiguration through two methods: full or partial reconfiguration.

A.8.1. Full FPGA Reconfiguration

A full FPGA reconfiguration requires a system reboot. The following table details the supported reconfiguration options:

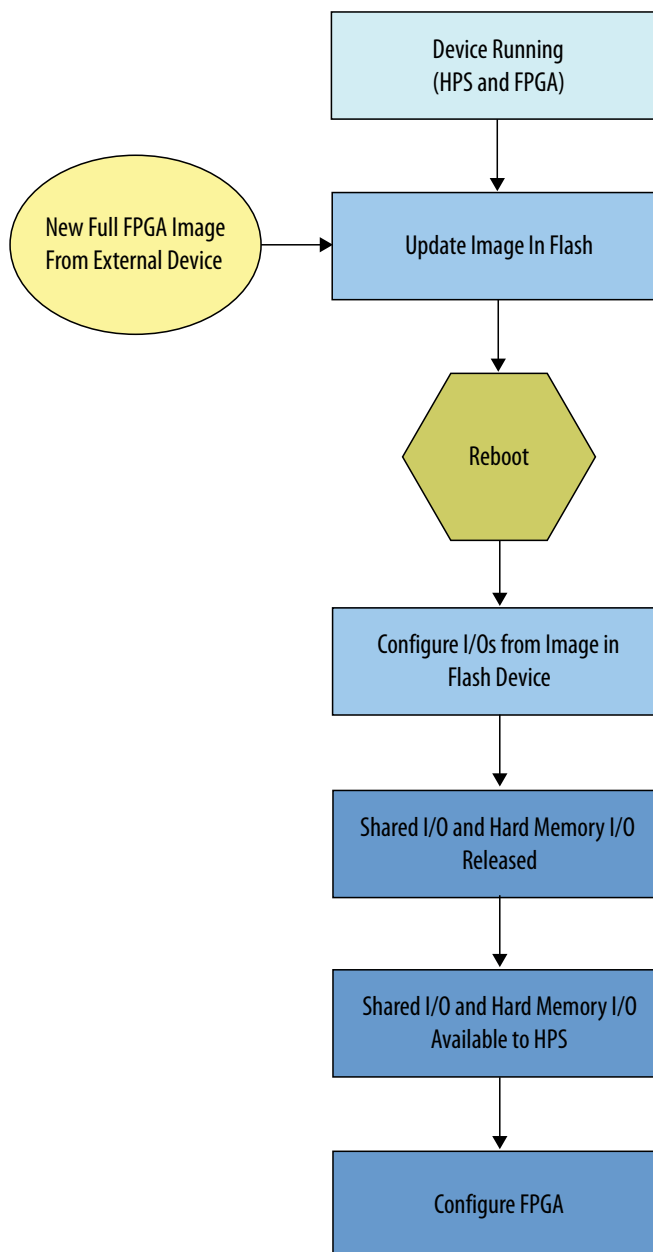

Table 355. Supported Reconfiguration Options

Reconfiguration Option	Configuration Method	HPS Reboot Required
FPGA Core Only	Partial Reconfiguration	No
FPGA and/or HPS Shared I/O ⁽⁶⁷⁾	Full Reconfiguration	Yes
FPGA Core + FPGA I/O + HPS Shared I/O ⁽⁶⁷⁾	Full Reconfiguration	Yes

If a new FPGA fabric image is required and performing a system reboot is acceptable, then you can update the FPGA image in flash and perform a full system reboot of both hardware and software before following the steps found in the "Arria 10 SoC FPGA Configuration Sequence Through FPGA Manager."

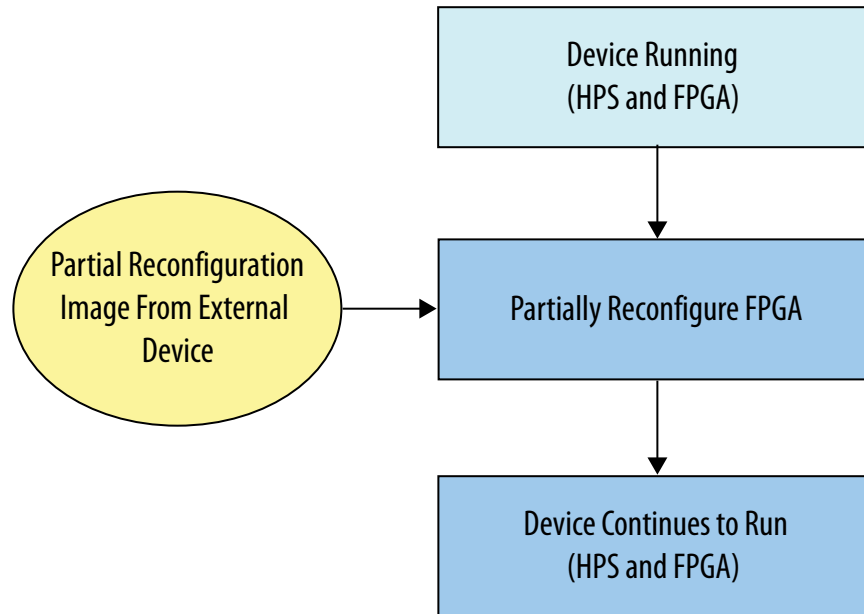

⁽⁶⁷⁾ HPS dedicated I/O are not affected by full reconfiguration.

Figure 219. Full FPGA Fabric Reconfiguration with System Reboot

If a new FPGA fabric image is required and performing a system reboot is unacceptable because the hard memory controller or shared I/O are being used by the HPS, then you can perform a reconfiguration using the available partial reconfiguration support. For the partial reconfiguration sequence, follow the steps found in the "Arria 10 SoC FPGA Partial Reconfiguration Sequence Through FPGA Manager" section.

Figure 220. Full FPGA Fabric Reconfiguration without System Reboot

Note: It is important that the HPS is not held in cold or warm reset indefinitely, otherwise the CSS will not be accessible to FPGA configuration sources.

A.8.2. Arria 10 SoC FPGA Partial Reconfiguration Sequence Through FPGA Manager

Partial reconfiguration allows you to reconfigure part of the device while other sections remain running. This implementation divides the design into a static region and a partial reconfiguration region.

- **Static Region:** Comprised of hard memory controller I/O, shared I/O, FPGA I/O and a portion of your FPGA design
- **Dynamic Region:** Remaining portion of FPGA design

The HPS performs partial reconfiguration while the FPGA portion of the device is in user mode. The following sequence suggests one way for software to perform a partial configuration. When using this sequence:

- If `f2s_pr_ready=1` and `f2s_pr_error=0` in the `imgcfg_stat` register of the FPGA Manager, begin at step 9.
- If the `f2s_pr_ready` bit in the `imgcfg_stat` register of the FPGA Manager is clear, then begin the sequence at step 1.

If an HPS warm reset occurs in the middle of a partial reconfiguration, software must repeat the steps for partial configuration. After an HPS cold reset, software must repeat the steps for [Arria 10 SoC FPGA Configuration Sequence Through FPGA Manager](#) on page 4680.

1. Read the `f2s_usermode` bit of the `imgcfg_stat` register in FPGA Manager to ensure that the FPGA is in user mode.
2. Read the `f2s_msel[2:0]` field in the `imgcfg_stat` register to verify that the configuration mode is the passive fast (000) or passive slow (001). The FPGA manager only supports passive parallel programming.
3. Set the `cdratio` bit of the `imgcfg_ctrl_02` register to match the characteristics of the partial reconfiguration image and configure the `cfgwidth` bit of the `imgcfg_ctrl_02` register to 0. Partial reconfiguration only supports 16-bit passive parallel programming.
4. Prepare for partial reconfiguration. Set the `en_cfg_ctrl` bit of the `imgcfg_ctrl_02` register to give the FPGA manager control of the configuration input signals.
 - a. Read and confirm that `s2f_pr_request=0` in the `imgcfg_ctrl_01` register and `s2f_nconfig=1` in the `imgcfg_ctrl_00` register.
 - b. Drive the chip select signal by clearing the `s2f_nce` bit in the `imgcfg_ctrl_01` register.
 - c. Enable overrides for configuration data and control by setting the `en_cfg_ctrl` bit in the `imgcfg_ctrl_02` to 1.
 - d. Disable overrides that are not used for partial reconfiguration by programming the following bits in the `imgcfg_ctrl_00` register:
 - `s2f_condone_oe = 0`
 - `s2f_nstatus_oe = 0`
 - `s2_nconfig = 1`
 - `s2f_nenable_condone = 1`
 - `s2f_nenable_nstatus = 1`
 - `s2f_nenable_nconfig = 0`
5. Enable HPS to override the DATA, DCLK, nCE and PR_REQUEST signals to the CSS by clearing the `s2f_nenable_config` bit in the `imgcfg_ctrl_01` register.
6. Run DCLK to clear any errors. Write a value of 0x100 to the `dclkcnt` register to generate 256 DCLK cycles. Poll the `dclkstat` register until `dcntdone=1`. You must implement a timeout in your software loop that either exits with an error or restarts at step 1 if `dcntdone` is not set after a period of time.
7. Initiate a partial reconfiguration request.
 - a. Set the `s2f_pr_request` bit of the `imgcfg_ctrl_01` register to assert PR_REQUEST
 - b. Write 0x7FF to the `dclkcnt` register.
 - c. Poll the `dclkstat` register until `dcntdone=1`. Again, you must implement a timeout in your software loop that either exits with an error or restarts at step 1 if `dcntdone` is not set after a period of time.

8. Poll the `f2s_pr_ready` bit and the `f2s_pr_error` bit in the `imgcfg_stat` register. When `f2s_pr_ready=1`, the `PR_READY` signal is asserted. Alternately, the FPGA Manager can be configured to generate an interrupt when the `PR_READY` signal is asserted. If `f2s_pr_error=1`, you cannot continue with partial reconfiguration because security is preventing the software from updating the configuration. Intel recommends that your software routine implement an exit with a timeout error when `f2s_pr_ready` and `f2s_pr_error` continue to read as 0 after ten register reads.
9. When the `PR_READY` signal is asserted, write the partial reconfiguration image to the `img_data_w` register in the FPGA Manager. You can also choose to use a DMA to transfer the configuration image from a peripheral device to the FPGA manager.
10. Poll the `imgcfg_stat` register to observe the `f2s_pr_done` and `f2s_pr_error` bits. When the `f2s_pr_done` bit is set, partial FPGA reconfiguration is complete. If `f2s_pr_done` or `f2s_pr_error` is not set to 1 after reading the `imgcfg_stat` register ten times, generate a timeout error and continue on to the next step.
11. Clear the `s2f_pr_request` bit of the `imgcfg_ctrl_01` register to deassert `PR_REQUEST`.
12. Poll the `dcntdone` bit of the `dclkstat` register until it reads as 1, which indicates that all the `DCLKs` have been sent.
13. Write a 1 to the `dcntdone` bit of the `dclkstat` register to clear the completed status flag.
14. Disable the `DATA` path and `DCLK` by clearing the `en_cfg_ctrl` bit of the `imgcfg_ctrl_02` register.
15. Disable the chip select. Set the `s2f_nce` bit in the `imgcfg_ctrl_01` register.
16. Disable overrides to the `nCONFIG`, `DATA` and `DCLK` signals by setting the `s2f_nenable_config` in the `imgcfg_ctrl_01` register.
17. Check that user mode is enabled and the configuration is done by checking that the bits below have the following values:
 - `f2s_usermode=1` in the `imgcfg_stat` register
 - `f2s_nstatus_pin=1` in the `imgcfg_stat` register
 - `f2s_condone_pin=1` in the `imgcfg_stat` register
